Prescribing Information
Patient Information Leaflet

1. NAME OF THE MEDICINAL PRODUCT

Rapamune

2. QUALITATIVE AND QUANTITATIVE COMPOSITION

Sirolimus (INN)

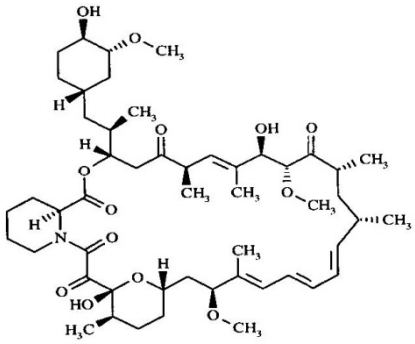
Rapamune (sirolimus) is an immunosuppressive agent. Sirolimus is a macrocyclic lactone produced by *Streptomyces hygroscopicus*.

Chemical Name

The chemical name of sirolimus (also known as rapamycin) is (3*S*,6*R*,7*E*,9*R*,10*R*,12*R*,14*S*,15*E*,17*E*,19*E*,21*S*,23*S*,26*R*,27*R*,34a*S*)-9,10,12,13,14,21,22,23,24,25,26,27,32,33,34,34a-hexadecahydro-9,27-dihydroxy-3-[(1*R*)-2-[(1*S*,3*R*,4*R*)-4-hydroxy-3-methoxycyclohexyl]-1-methylethyl]-10,21-dimethoxy-6,8,12,14,20,26-hexamethyl-23,27-epoxy-3*H*-pyrido[2,1-*c*][1,4] oxaazacyclohentriacontine-1,5,11,28,29 (4*H*,6*H*,31*H*)-pentone.

Structure

The structural formula of sirolimus is shown below.



Molecular Formula

Its molecular formula is $C_{51}H_{79}NO_{13}$

Molecular Weight

Its molecular weight is 914.2.

Physical Characteristics

Sirolimus is a white to off-white powder and is insoluble in water, but freely soluble in benzyl alcohol, chloroform, acetone, and acetonitrile.

Composition and Pharmaceutical Characteristics

Rapamune is available for administration as a tan, triangular-shaped tablet containing 0.5 mg sirolimus, and as a white, triangular-shaped tablet containing 1 mg sirolimus.

Excipients: see **Section 6.1. List of excipients.**

3. PHARMACEUTICAL FORM

Tablets.

4. CLINICAL PARTICULARS

4.1. Therapeutic indications

Rapamune (sirolimus) is indicated for the prophylaxis of organ rejection in patients receiving renal transplants.

In patients at low to moderate immunologic risk, it is recommended that Rapamune be used initially in a regimen with cyclosporine and corticosteroids.

Cyclosporine should be withdrawn 2 to 4 months after transplantation and the Rapamune dose should be increased to reach recommended blood concentrations (see **Section 4.2. Posology and method of administration**). Cyclosporine withdrawal has not been studied in patients with Banff 93 Grade III acute rejection or vascular rejection prior to cyclosporine withdrawal, those who are dialysis-dependent, or with serum creatinine >4.5 mg/dL, Black patients, renal re-transplants, multi-organ transplants, or patients with high-panel reactive antibodies (see **Section 5.1 Pharmacodynamic properties - Clinical Trials Data on Efficacy**).

4.2. Posology and method of administration

4.2.1. Dosage

Bioavailability has not been determined for tablets after they have been crushed, chewed, or split and therefore, this cannot be recommended.

Only physicians experienced in immunosuppressive therapy and management of organ transplant patients should prescribe Rapamune. Patients receiving the drug should be managed in facilities equipped and staffed with adequate laboratory and supportive medical resources. The physician responsible for maintenance therapy should have complete information requisite for the follow-up of the patient.

Patients at Low to Moderate Immunologic Risk

It is recommended that Rapamune be used initially in a regimen with cyclosporine and corticosteroids. Cyclosporine should be withdrawn 2 to 4 months after renal transplantation in patients at low to moderate immunological risk, and the Rapamune dose should be increased to reach recommended blood concentrations. Cyclosporine withdrawal has not been studied in patients with Banff 93 Grade III acute rejection or vascular rejection prior to cyclosporine withdrawal, those who are dialysis-dependent, or with serum creatinine >4.5 mg/dL, Black

patients, re-transplants, multi-organ transplants, or patients with high-panel reactive antibodies (see **Section 4.1. Therapeutic indications** and **Section 5.1. Pharmacodynamic properties - Clinical Trials Data on Efficacy**).

Adults

Rapamune with Cyclosporine Therapy
The usual dosage regimen for Rapamune is a 6 mg oral loading dose, administered as soon as possible after transplantation, followed by 2 mg once daily. The Rapamune dose should then be individualized, to obtain whole blood trough levels of 4 to 12 ng/mL.

Rapamune is to be administered orally once daily.

Rapamune Maintenance Regimen with Cyclosporine Withdrawal
Initially, patients should be receiving Rapamune and cyclosporine combination therapy. At 2 to 4 months following transplantation, cyclosporine should be progressively discontinued over 4 to 8 weeks and the Rapamune dose should be adjusted to obtain whole blood trough concentrations within the range of 16 to 24 ng/mL (chromatographic method) for the first year following transplantation. Thereafter, the target sirolimus concentrations should be 12 to 20 ng/mL (chromatographic method). The actual observations at Year 1 and 5 (see below) were close to these ranges (see **Section 4.2.2. Sirolimus whole blood trough level monitoring**). Therapeutic drug monitoring should not be the sole basis for adjusting Rapamune therapy. Careful attention should be made to clinical signs/symptoms, tissue biopsy, and laboratory parameters. Cyclosporine inhibits the metabolism and transport of sirolimus, and consequently, sirolimus concentrations will decrease when cyclosporine is discontinued unless the Rapamune dose is increased. The Rapamune dose will need to be approximately 4-fold higher to account for both the absence of the pharmacokinetic interaction (approximately 2-fold increase) and the augmented immunosuppressive requirement in the absence of cyclosporine (approximately 2-fold increase).

Patients at High Immunologic Risk

It is recommended that Rapamune be taken 4 hours after cyclosporine microemulsion [cyclosporine, USP] administration.

Use in Children

Safety and efficacy of Rapamune in pediatric patients below the age of 13 years have not been established. It is recommended that sirolimus whole blood trough levels be monitored if used in pediatric patients <13 years of age.

Use in Elderly Patient

No dose adjustment is required in elderly patients.

Clinical studies of Rapamune did not include sufficient number of patients aged 65 and over to determine whether they will respond differently than younger patients. Sirolimus trough concentration data in 35 renal transplant patients >65 years of age were similar to those in the adult population (n=822) from 18 to 65 years of age.

Patients with Renal Impairment

No dosage adjustment is required.

Patients with Hepatic Impairment

In patients with hepatic impairment, it is recommended that the maintenance dose of Rapamune be reduced by approximately one-third to one-half. It is not necessary to modify the Rapamune loading dose.

The pharmacokinetics of Rapamune has not been studied in patients with severe hepatic impairment.

In patients with hepatic impairment, it is recommended that sirolimus whole blood trough levels be monitored.

4.2.2. Sirolimus whole blood trough level monitoring

Blood sirolimus trough levels should be monitored:

(1) in patients with hepatic impairment
(2) in patients receiving concentration-controlled Rapamune
(3) in pediatric patients
(4) during concurrent administration of inhibitors and inducers of CYP3A4 and P-glycoprotein (P-gp)
(5) if cyclosporine dosing is markedly reduced, or if cyclosporine is discontinued.

Therapeutic drug monitoring should not be the sole basis for adjusting sirolimus therapy. Careful attention should be made to clinical signs/symptoms, tissue biopsies, and laboratory parameters.

Assay Methodology
The recommended 24-hour trough concentration ranges for sirolimus are based on chromatographic methods. Several assay methodologies have been used to measure the whole blood concentrations of sirolimus. Currently in clinical practice, sirolimus whole blood concentrations are being measured by both chromatographic and immunoassay methodologies. The concentration values obtained by these different methodologies are not interchangeable. Adjustments to the targeted range should be made according to the assay being utilized to determine the sirolimus trough concentration. Since results are assay and laboratory dependent, and the results may change over time, adjustments to the target therapeutic range must be made with a detailed knowledge of the site-specific assay used. A discussion of the different assay methods is contained in Clinical Therapeutics, Volume 22, Supplement B, April 2000.

4.2.3. Mode of administration

Rapamune is intended for oral administration only.

Rapamune must be taken consistently with or without food to minimize variation in drug absorption.

4.3. Contraindications

Rapamune is contraindicated in patients with a hypersensitivity to sirolimus or its derivatives or any excipients in the formulation.

4.4. Special warnings and precautions for use

Immunosuppression increases the susceptibility to infection and the development of lymphoma and other malignancies, particularly of the skin, (see **Section 4.8. Undesirable effects**). Oversuppression of the immune system can also increase susceptibility to opportunistic infections, sepsis, and fatal infections. Only physicians experienced in immunosuppressive therapy and management of organ transplant patients should use Rapamune. Patients receiving the drug should be managed in facilities equipped and staffed with adequate laboratory and supportive medical resources. The physician responsible for maintenance therapy should have complete information requisite for the follow-up of the patient.

Hypersensitivity reactions, including anaphylactic/anaphylactoid reactions, angioedema, exfoliative dermatitis, and hypersensitivity vasculitis, have been associated with the administration of sirolimus (see **Section 4.8. Undesirable effects**).

The safety and efficacy of Rapamune as immunosuppressive therapy have not been established in liver or lung transplant patients, and therefore, such use is not recommended.

Liver Transplantation
Excess Mortality, Graft Loss, and Hepatic Artery Thrombosis (HAT): The use of Rapamune in combination with tacrolimus was associated with excess mortality and graft loss in a study in *de novo* liver transplant recipients. Many of these patients had evidence of infection at or near the time of death. In this and another study in *de novo* liver transplant recipients, the use of Rapamune in combination with cyclosporine or tacrolimus was associated with an increase in HAT; most cases of HAT occurred within 30 days post-transplantation and most led to graft loss or death.

A clinical study in liver transplant patients randomized to conversion to a sirolimus-based regimen versus continuation of a calcineurin inhibitors (CNI)-based regimen 6-144 months post-liver transplantation demonstrated an increased number of deaths in the sirolimus conversion group compared to the CNI continuation group, although the difference was not statistically significant (see **Section 5.1. Pharmacodynamic properties - Clinical Trials Data on Efficacy**).

Lung Transplantation
Bronchial Anastomotic Dehiscence: Cases of bronchial anastomotic dehiscence, most fatal, have been reported in *de novo* lung transplant patients when Rapamune has been used as part of an immunosuppressive regimen.

Drug-Drug Interactions
Co-administration of Rapamune with strong inhibitors of CYP3A4 and/or P-gp (such as ketoconazole, voriconazole, itraconazole, erythromycin, telithromycin, or clarithromycin) or strong inducers of CYP3A4 and/or P-gp (such as rifampin or rifabutin) is not recommended. Sirolimus is extensively metabolized by the CYP3A4 isozyme in the intestinal wall and liver. Inhibitors of CYP3A4 decrease the metabolism of sirolimus and increase sirolimus levels.

Inducers of CYP3A4 increase the metabolism of sirolimus and decrease sirolimus levels (see **Section 4.5. Interaction with other medicinal products and other forms of interaction**).

There have been reports of increased blood levels of sirolimus during concomitant use with cannabidiol. Caution should be used when cannabidiol and Rapamune are co-administered, closely monitor sirolimus blood levels and for adverse events suggestive of sirolimus toxicity (see **Sections 4.2.2. Sirolimus whole blood trough level monitoring** and **4.5.4. Cannabidiol**).

Renal Function

In Studies 1 and 2, from Month 6 through Months 24 and 36, respectively, mean serum creatinine was increased and mean glomerular filtration rate was decreased in patients treated with Rapamune and cyclosporine compared with those treated with cyclosporine and placebo or azathioprine controls. The rate of decline in renal function was greater in patients receiving Rapamune and cyclosporine compared with control therapies (see **Section 5.1. Pharmacodynamic properties - Clinical Trials Data on Efficacy**). Renal function should be closely monitored during the co-administration of Rapamune with cyclosporine because long-term administration of the combination has been associated with deterioration of renal function. Renal function should also be closely monitored during the co-administration of Rapamune with tacrolimus. Appropriate adjustment of the immunosuppression regimen, including discontinuation of Rapamune and/or cyclosporine and/or tacrolimus, should be considered in patients with elevated or increasing serum creatinine levels. Caution should be exercised when using other drugs which are known to impair renal function.

In clinical trials, Rapamune has been administered concurrently with corticosteroids and with cyclosporine. The formulations of cyclosporine include:

Sandimmune® Injection (cyclosporine injection)
Sandimmune® Oral Solution (cyclosporine oral solution)
Sandimmune® Soft Gelatin Capsules (cyclosporine capsules)
Neoral® Soft Gelatin Capsules (cyclosporine capsules)
Neoral® Oral Solution (cyclosporine oral solution)

The efficacy and safety of the use of Rapamune in combination with other immunosuppressive agents has not been determined.

General

Lymphocele, a known surgical complication of renal transplantation, occurred significantly more often in a dose-related fashion in Rapamune-treated patients. Appropriate post-operative measures should be considered to minimize this complication.

Wound Healing and Fluid Accumulation

Mammalian Target of Rapamycin (mTOR) inhibitors such as sirolimus have been shown *in vitro* to inhibit production of certain growth factors that may affect angiogenesis, fibroblast proliferation, and vascular permeability. There have been reports of impaired or delayed wound healing in patients receiving Rapamune, including lymphocele and wound dehiscence. Patients with a body mass index (BMI) greater than 30 kg/m^2 may be at increased risk of abnormal wound healing based on data from the medical literature.

There have also been reports of fluid accumulation, including peripheral edema, lymphedema, pleural effusion and pericardial effusions (including hemodynamically significant effusions in children and adults), in patients receiving Rapamune.

Skin Malignancies

Immunosuppression increases the susceptibility to the development of lymphoma and other malignancies, particularly of the skin. Therefore, patients taking Rapamune should limit exposure to sunlight and UV light by wearing protective clothing and using a sunscreen with a high protective factor (see **Section 4.8. Undesirable effects**).

Hyperlipidemia

The use of Rapamune may lead to more frequently increased serum cholesterol and triglycerides that may require treatment compared with azathioprine or placebo controls. Patients must be monitored for hyperlipidemia.

In phase III clinical trials, in *de novo* renal transplant recipients who began the study with normal, fasting, total serum triglycerides (fasting serum triglycerides <200 mg/dL), there was an increased incidence of hypertriglyceridemia (fasting serum triglycerides >500 mg/dL) in patients receiving Rapamune 2 mg and Rapamune 5 mg compared to azathioprine and placebo controls.

Treatment of new-onset hypercholesterolemia with lipid-lowering agents was required in 42 – 52% of patients enrolled in the Rapamune arms of the study compared to 16% of patients in the placebo arm and 22% of patients in the azathioprine arm.

Renal transplant patients have a higher prevalence of clinically significant hyperlipidemia. Accordingly, the risk/benefit should be carefully considered in patients with established hyperlipidemia before initiating an immunosuppressive regimen including Rapamune.

Any patient who is administered Rapamune should be monitored for hyperlipidemia using laboratory tests and if hyperlipidemia is detected, subsequent interventions such as diet, exercise, and lipid-lowering agents, as outlined by the National Cholesterol Education Program guidelines, should be initiated.

Rhabdomyolysis

In clinical trials, the concomitant administration of Rapamune and HMG-CoA reductase inhibitors and/or fibrates was well tolerated. During Rapamune therapy with or without cyclosporine, patients should be monitored for elevated lipids, and patients administered an HMG-CoA reductase inhibitor and/or fibrate should be monitored for the possible development of rhabdomyolysis and other adverse effects as described in the respective labeling for these agents.

Rapamune Following Cyclosporine Withdrawal

In a study that compared a regimen of Rapamune and cyclosporine to one in which cyclosporine was withdrawn 2-4 months post-transplantation, those in whom cyclosporine was not withdrawn had significantly higher serum creatinine levels and significantly lower glomerular filtration rates at 12 months through 60 months, and significantly lower graft survival at 48 months, the point at which it was decided by the sponsor to discontinue subjects from assigned therapy in the Rapamune and cyclosporine arm. When the protocol was amended all subjects had reached 48 months and some completed the 60 months of the study.

In patients at low to moderate immunologic risk, continuation of combination therapy with cyclosporine beyond 4 months following transplantation should only be considered when the benefits outweigh the risks of this combination for individual patients.

In patients with delayed graft function, Rapamune may delay recovery of renal function.

Proteinuria

Periodic quantitative monitoring of urinary protein excretion is recommended. In a study evaluation conversion from CNI to Rapamune in maintenance renal transplant patients 6 – 120 months post-transplant, increased urinary protein excretion was commonly observed from the 6 through 24 month after conversion of Rapamune compared with CNI continuation (23.6% versus 12.8%, respectively) (see **Section 4.8. Undesirable effects** and **Section 5.1. Pharmacodynamic properties - Clinical Trials Data on Efficacy**). Those patients in the highest quartile of urinary protein excretion prior to Rapamune conversion (urinary protein to creatinine ratio ≥0.27) were those whose protein excretion increased the most after conversion. New-onset nephrosis (nephrotic syndrome) was also reported in 2% of the patients in the study. Reduction in the degree of urinary protein excretion was observed for individual patients following discontinuation of Rapamune. The safety and efficacy of conversion from calcineurin inhibitors to sirolimus in maintenance renal transplant patients have not been established.

Conversion to Rapamune in Patients with Glomerular Filtration Rate <40 mL/min

In a study evaluating conversion from CNI to Rapamune in maintenance renal transplant patients 6-120 months post-transplant (see **Section 5.1. Pharmacodynamic properties - Clinical Trials Data on Efficacy**), in a stratum of the Rapamune treatment arm with a calculated glomerular filtration rate of less than 40 mL/min, there was a higher rate of serious adverse events, including pneumonia, acute rejection, graft loss and death. The safety and efficacy of conversion from calcineurin inhibitors to Rapamune in maintenance renal transplant patients have not been established.

De Novo Use without Calcineurin Inhibitor (CNI)

The safety and efficacy of *de novo* use of Rapamune without a calcineurin inhibitor (CNI) is not established in renal transplant patients. In two multi-center clinical studies, *de novo* renal transplant patients treated with Rapamune, MMF, steroids, and an IL-2 receptor antagonist had significantly higher acute rejection rates and numerically higher death rates compared to patients treated with a calcineurin inhibitor, MMF, steroids, and IL-2 receptor antagonist. A benefit, in terms of better renal function, was not apparent in the treatment arms with *de novo* use of Rapamune without a CNI. It should be noted that an abbreviated schedule of administration of daclizumab was employed in one of the studies.

Calcineurin Inhibitor-induced Hemolytic Uremic Syndrome/Thrombotic Thrombocytopenic Purpura/Thrombotic Microangiopathy (HUS/TTP/TMA)

The concomitant use of sirolimus with a calcineurin inhibitor may increase the risk of calcineurin inhibitor-induced HUS/TTP/TMA.

Angioedema

The concomitant administration of Rapamune and angiotensin-converting enzyme (ACE) inhibitors has resulted in angioneurotic edema-type reactions.

Elevated sirolimus levels (with/without concomitant ACE inhibitors) may also potentiate angioedema (see **Section 4.5.1. Inhibitors and inducers of cytochrome P450 3A4 (CYP3A4) and P-glycoprotein (P-gp)**). In some cases, the angioedema has resolved upon discontinuation or dose reduction of Rapamune.

Interstitial Lung Disease

Cases of interstitial lung disease (including pneumonitis, and infrequently bronchiolitis obliterans organizing pneumonia [BOOP] and pulmonary fibrosis), some fatal, with no identified infectious etiology have occurred in patients receiving immunosuppressive regimens including Rapamune. In some cases, the interstitial lung disease has resolved upon discontinuation or dose reduction of Rapamune. The risk may be increased as the trough sirolimus levels increases (see **Section 4.8. Undesirable effects - Interstitial Lung Disease**).

Latent Viral Infections

Patients treated with immunosuppressants, including Rapamune, are at increased risk for opportunistic infections, including activation of latent viral infections. Among these conditions is BK virus associated nephropathy and JC virus associated progressive multifocal leukoencephalopathy (PML). These infections are often related to a high total immunosuppressive burden and may lead to serious or fatal outcomes, including graft loss. Physicians should consider latent viral infections in the differential diagnosis in immunosuppressed patients with deteriorating renal function or neurological symptoms (see **Section 4.8. Undesirable effects - Latent Viral Infections**).

Antimicrobial Prophylaxis

Antimicrobial prophylaxis for *Pneumocystis carinii* pneumonia should be administered for 1 year following transplantation.

Cytomegalovirus (CMV) prophylaxis is recommended for 3 months after transplantation, particularly for patients at increased risk for CMV infection.

Contraception

Women of childbearing potential should be informed of the potential risks during pregnancy and that effective contraception must be initiated before Rapamune therapy, and maintained during Rapamune therapy and for 12 weeks after Rapamune therapy has been stopped.

Use in High-Risk Patients

The safety and efficacy of cyclosporine withdrawal in high-risk renal transplant patients have not been adequately studied and such use is therefore, not recommended. This includes patients with Banff 93 Grade III acute rejection or vascular rejection prior to cyclosporine withdrawal, those who are dialysis-dependent or with serum creatinine >4.5 mg/dL, Black patients, renal re-transplants, multi-organ transplants, and patients with a high panel of reactive antibodies (see **Section 4.1. Therapeutic indications** and **Section 5.1. Pharmacodynamic properties - Clinical Trials Data on Efficacy**).

Laboratory Tests

Whole blood sirolimus levels should be monitored in all patients. It is prudent to monitor blood sirolimus levels in patients likely to have altered drug metabolism in patients ≥13 years who weigh less than 40 kg, in patients with hepatic impairment, and during concurrent administration of potent CYP3A4 inducers and inhibitors (see **Section 4.5. Interaction with other medicinal products and other forms of interaction**).

4.5. Interaction with other medicinal products and other forms of interaction

Sirolimus is known to be a substrate for both cytochrome CYP3A4 and P-glycoprotein (P-gp). The pharmacokinetic interaction between sirolimus and concomitantly administered drugs is discussed below. Drug interaction studies have not been conducted with drugs other than those described below.

4.5.1. Inhibitors and inducers of cytochrome P450 3A4 (CYP3A4) and P-glycoprotein (P-gp)

Co-administration of Rapamune with strong inhibitors of CYP3A4 (such as ketoconazole, voriconazole, itraconazole, telithromycin, or clarithromycin) or inducers of CYP3A4 (such as rifampin or rifabutin) is not recommended. Sirolimus is extensively metabolized by the CYP3A4 isoenzyme intestinal wall and liver and undergoes counter-transport from enterocytes of the small intestine by the P-glycoprotein (P-gp) drug-efflux pump. Therefore, absorption and the subsequent elimination of systemically absorbed sirolimus may be influenced by drugs that affect these proteins. Inhibitors of CYP3A4 and P-gp may increase sirolimus levels. Inducers of CYP3A4 and P-gp may decrease sirolimus levels. In patients in whom strong inhibitors or inducers of CYP3A4 and P-gp are indicated, alternative therapeutic agents with less potential for inhibition or induction of CYP3A4 and P-gp should be considered.

Substances that inhibit CYP3A4 include but are not limited to:
- Calcium channel blockers: diltiazem, nicardipine, verapamil
- Antifungal agents: clotrimazole, fluconazole, itraconazole, ketoconazole, voriconazole
- Antibiotics: clarithromycin, erythromycin, telithromycin, troleandomycin
- Gastrointestinal prokinetic agents: cisapride, metoclopramide
- Other drugs: bromocriptine, cimetidine, cyclosporine, danazol, letermovir, protease inhibitors (e.g., for HIV and hepatitis C that include drugs such as ritonavir, indinavir, boceprevir, and telaprevir)
- Grapefruit juice

Substances that induce CYP3A4 include but are not limited to:
- Anticonvulsants: carbamazepine, phenobarbital, phenytoin
- Antibiotics: rifabutin, rifampicin, rifapentine
- Herbal preparations: St. John's Wort (*Hypericum perforatum*, hypericin)

The pharmacokinetic interaction between sirolimus and concomitantly administered drugs is discussed below. Drug interaction studies have been conducted with the following:

<u>Diltiazem</u>
Diltiazem is a substrate and inhibitor of CYP3A4 and P-gp. Sirolimus levels should be monitored and a dose reduction may be necessary if diltiazem is co-administered.

The simultaneous oral administration of 10 mg of sirolimus oral solution and 120 mg of diltiazem to 18 healthy volunteers significantly increased the bioavailability of sirolimus. Sirolimus C_{max}, t_{max}, and AUC were increased 1.4-, 1.3-, and 1.6-fold, respectively. Sirolimus did not affect the pharmacokinetics of either diltiazem or its metabolites desacetyldiltiazem and desmethyldiltiazem.

Verapamil
Verapamil is an inhibitor of CYP3A4 and P-gp. Sirolimus levels should be monitored and appropriate dose reduction of both medications should be considered.

Multiple-dose administration of verapamil and Rapamune oral solution significantly affected the rate and extent of absorption of both drugs. In a study of 25 healthy volunteers, whole blood sirolimus C_{max}, t_{max}, and AUC were increased 2.3-fold, 1.1-fold, and 2.2-fold, respectively. Plasma S-(-) verapamil C_{max} and AUC were both increased 1.5-fold, and t_{max} was decreased 24%.

Erythromycin
Erythromycin is an inhibitor of CYP3A4 and P-gp. Sirolimus levels should be monitored and appropriate dose reductions of both medications should be considered.

Multiple-dose administration of erythromycin ethylsuccinate and Rapamune oral solution significantly increased the rate and extent of absorption of both drugs. In a study of 24 healthy volunteers, whole blood sirolimus C_{max}, t_{max}, and AUC were increased 4.4-fold, 1.4-fold, and 4.2-fold, respectively. The C_{max}, t_{max}, and AUC of plasma erythromycin base were increased 1.6-fold, 1.3-fold, and 1.7-fold, respectively.

Ketoconazole
Ketoconazole is a strong inhibitor of CYP3A4 and P-gp. Co-administration of Rapamune and ketoconazole is not recommended.

In a study of 24 healthy volunteers, it was found that multiple-dose ketoconazole administration significantly affected the rate and extent of absorption and sirolimus exposure after administration of Rapamune Oral Solution, as reflected by increases in sirolimus C_{max}, t_{max}, and AUC of 4.4-fold, 1.4-fold, and 10.9-fold, respectively. However, the terminal $t_{1/2}$ of sirolimus was not changed. Single-dose Rapamune did not affect steady-state 12-hour plasma ketoconazole concentrations.

Rifampicin
Rifampin is a strong inducer of CYP3A4 and P-gp. Co-administration of Rapamune and rifampin is not recommended.

Pretreatment of 14 healthy volunteers with multiple doses of rifampicin (600 mg daily for 14 days) followed by a single 20 mg dose of Rapamune oral solution, greatly increased sirolimus oral-dose clearance by 5.5-fold (range=2.8 to 10), which represents mean decreases in AUC and C_{max} of about 82% and 71%, respectively.

4.5.2. Non-interactions

Clinically significant pharmacokinetic drug-drug interactions were not observed in studies of drugs listed below. A synopsis of the type of study performed for each drug is provided. Sirolimus and these drugs may be co-administered without dose adjustments.

- **Acyclovir:** Acyclovir, 200 mg, was administered once daily for 3 days followed by a single 10 mg dose of sirolimus oral solution on Day 3 in 20 adult healthy volunteers.

- **Atorvastatin:** Atorvastatin, 20 mg, was given daily for 10 days to 23 healthy volunteers, followed by a combined regimen of sirolimus oral solution, 2 mg, and atorvastatin, 20 mg, for 5 days.

- **Digoxin:** Digoxin, 0.25 mg, was administered daily for 8 days and a single 10 mg dose of sirolimus oral solution was given on Day 8 to 24 healthy volunteers.

- **Glyburide:** A single 5 mg dose of glyburide and a single 10 mg dose of sirolimus oral solution were administered to 24 healthy volunteers. Sirolimus did not affect the hypoglycemic action of glyburide.

- **Nifedipine:** A single 60 mg dose of nifedipine and a single 10 mg dose of sirolimus oral solution were administered to 24 healthy volunteers.

- **Norgestrel/ethinyl estradiol (Lo/Ovral®):** Sirolimus oral solution, 2 mg, was given daily for 7 days to 21 healthy female volunteers on norgestrel/ethinyl estradiol.

- **Prednisone:** Pharmacokinetic information was obtained from 42 stable renal transplant patients receiving daily doses of prednisone (5-20 mg/day) and either single or multiple doses of sirolimus oral solution (0.5-5 mg/m^2 q 12h).

- **Sulfamethoxazole/trimethoprim (Bactrim®):** A single oral dose of sulfamethoxazole (400 mg)/trimethoprim, (80 mg) was given to 15 renal transplant patients receiving daily oral doses of sirolimus (8 to 25 mg/m^2).

4.5.3. Cyclosporine

Cyclosporine is a substrate and inhibitor of CYP3A4 and P-gp.

Patients administered sirolimus with cyclosporine together with HMG-CoA reductase inhibitor and/or fibrate should be monitored for the development of rhabdomyolysis (see **Section 4.4. Special warnings and precautions for use**).

Cyclosporine microemulsion (cyclosporine, USP)

It is recommended that Rapamune be taken 4 hours after cyclosporine microemulsion (cyclosporine, USP) administration.

In a single-dose drug-drug interaction study, 24 healthy volunteers were administered 10 mg Rapamune oral solution either simultaneously or 4 hours after a 300 mg dose of cyclosporine microemulsion (cyclosporine, USP). For simultaneous administration, the mean C_{max} and AUC of sirolimus were increased by 116% and 230%, respectively, relative to administration of sirolimus alone. However, when given 4 hours after cyclosporine microemulsion (cyclosporine, USP) administration, sirolimus C_{max} and AUC were increased by 37% and 80%, respectively, compared to administration of Rapamune alone.

In an otherwise identical study, Rapamune was administered as a 10 mg dose by tablet. For simultaneous administration, mean C_{max} and AUC were increased by 6.1-fold and 2.5-fold, respectively, relative to administration of Rapamune alone. However, when given 4 hours after

cyclosporine microemulsion (cyclosporine, USP) administration, sirolimus C_{max} and AUC were both increased by only 33% compared with administration of Rapamune alone.

After multiple-dose administration of Rapamune by oral solution given 4 hours after cyclosporine microemulsion (cyclosporine, USP) in renal post-transplant patients over 6 months, cyclosporine oral-dose clearance was reduced, and lower doses of cyclosporine microemulsion (cyclosporine, USP) were needed to maintain target cyclosporine concentrations.

Rapamune Oral Solution: In a single dose drug-drug interaction study, 24 healthy volunteers were administered 5 mg Rapamune either simultaneously or 2 hours before and after a 300 mg dose of cyclosporine microemulsion (cyclosporine, USP). For simultaneous administration, the mean C_{max} and AUC of sirolimus were increased by 117% and 183%, respectively, relative to administration of Rapamune alone. When given 2 hours after cyclosporine microemulsion (cyclosporine, USP) administration, sirolimus C_{max} and AUC were increased by 126% and 141%, respectively, compared to administration of Rapamune alone. When given 2 hours before cyclosporine microemulsion (cyclosporine, USP) administration, sirolimus C_{max} and AUC were not affected.

Sandimmune® Soft Gelatin Capsules (cyclosporine capsules) are not bioequivalent to Neoral® Soft Gelatin Capsules (cyclosporine capsules) and should not be used interchangeably.

Cyclosporine oral solution

In a multiple-dose study in 150 psoriasis patients, sirolimus 0.5, 1.5 and 3 mg/m^2/day was administered simultaneously with Sandimmune® Oral Solution (cyclosporine oral solution) 1.25 mg/kg/day. The increase in average sirolimus trough concentrations ranged between 67% to 86% relative to when sirolimus was administered without cyclosporine. The intersubject variability (%CV) for sirolimus trough concentrations ranged from 39.7% to 68.7%. There was no significant effect of multiple-dose sirolimus on cyclosporine trough concentrations following Sandimmune® Oral Solution (cyclosporine oral solution) administration. However, the (%CV) was higher (range 85.9% - 165%) than those from previous studies.

Sandimmune® Oral Solution (cyclosporine oral solution) is not bioequivalent to Neoral® Oral Solution (cyclosporine oral solution), and should not be used interchangeably. Although there is no published data comparing Sandimmune® Oral Solution (cyclosporine oral solution) to SandCya® Oral Solution (cyclosporine oral solution), they should not be used interchangeably.

4.5.4. Cannabidiol

There have been reports of increased blood levels of sirolimus during concomitant use with cannabidiol. Caution should be used when cannabidiol and Rapamune are co-administered, closely monitor sirolimus blood levels and for adverse events suggestive of sirolimus toxicity (see **Sections 4.2.2. Sirolimus whole blood trough level monitoring** and **4.4. Special warnings and precautions for use**).

4.5.5. HMG-CoA reductase inhibitors, fibrates

Patients administered Rapamune with HMG-CoA reductase inhibitors and/or fibrates should be monitored for the development of rhabdomyolysis (see **Section 4.4. Special warnings and precautions for use**).

4.5.6. Calcineurin inhibitors

Calcineurin inhibitor-induced hemolytic uremic syndrome/thrombotic thrombocytopenic purpura/thrombotic microangiopathy (HUS/TTP/TMA) has been reported in patients receiving sirolimus with a calcineurin inhibitor (see **Section 4.4. Special warnings and precautions for use**).

4.5.7. Vaccination

Immunosuppressants may affect response to vaccination. During treatment with immunosuppressants, including Rapamune, vaccination may be less effective. The use of live vaccines should be avoided during treatment with Rapamune.

4.5.8. Food

The bioavailability of sirolimus is affected by concomitant food intake. Rapamune® should be taken consistently with or without food to minimize blood level variability.

Grapefruit juice reduces CYP3A4-mediated drug metabolism and potentially enhances P-gp-mediated drug counter-transport from enterocytes of the small intestines. This juice must not be taken with Rapamune.

4.5.9. Interference with laboratory and other diagnostic tests

There are no studies on the interactions of Rapamune in commonly employed clinical laboratory tests.

4.6. Pregnancy and lactation

Pregnancy

There are no studies of Rapamune use in pregnant women. In animal studies, embryo/fetal toxicity was manifested as mortality and reduced fetal weights (with associated delays in skeletal ossification) (see **Section 5.3. Preclinical safety data**).

Rapamune should be used during pregnancy only if the potential benefit outweighs the potential risk to the embryo/fetus (see **Section 4.4. Special warnings and precautions for use**).

Lactation

Rapamune is excreted in trace amounts in milk of lactating rats. It is not known whether sirolimus is excreted in human milk. Because many drugs are excreted into human milk and because of the potential for adverse reactions in nursing infants from sirolimus, a decision

should be made whether to discontinue nursing or to discontinue the drug, taking into account the importance of the drug to the mother.

4.7. Effects on ability to drive and use machines

No studies on the effects on the ability to drive and use machines have been performed.

4.8. Undesirable effects

Rapamune Oral Solution: The incidence of adverse reactions was determined in two randomized, double-blind, multicenter controlled trials in which 499 renal transplant patients received Rapamune Oral Solution 2 mg/day, 477 received Rapamune Oral Solution 5 mg/day, 160 received azathioprine, and 124 received placebo. All patients were treated with cyclosporine and corticosteroids. Data (≥12 months post-transplant) presented in the table below show the adverse reactions that occurred in any treatment group with an incidence of ≥20%.

Specific adverse reactions associated with the administration of Rapamune Oral Solution occurred at a significantly higher frequency than in the respective control group. For both Rapamune Oral Solution 2 mg/day and 5 mg/day these include hypercholesterolemia, hyperlipidemia, hypertension, and rash; for Rapamune Oral Solution 2 mg/day acne; and for Rapamune Oral Solution 5 mg/day anemia, arthralgia, diarrhea, hypokalemia, and thrombocytopenia. The elevations of triglycerides and cholesterol and decreases in platelets and hemoglobin occurred in a dose-related manner in patients receiving Rapamune.

Patients maintained on Rapamune Oral Solution 5 mg/day, when compared with patients on Rapamune Oral Solution 2 mg/day, demonstrated an increased incidence of the following adverse events: anemia, leukopenia, thrombocytopenia, hypokalemia, hyperlipidemia, fever, and diarrhea.

In general, adverse events related to the administration of Rapamune were dependent on dose/concentration.

ADVERSE EVENTS OCCURRING AT A FREQUENCY OF ≥20% IN ANY TREATMENT GROUP IN PREVENTION OF ACUTE RENAL REJECTION TRIALS (%)[a] AT ≥12 MONTHS POST-TRANSPLANTATION FOR STUDIES 1 AND 2

[a]: Patients received cyclosporine and corticosteroids.

At 12 months, there were no significant differences in incidence rates for clinically important opportunistic or common transplant-related infections across treatment groups, with the

exception of mucosal infections with *Herpes simplex*, which occurred at a significantly greater rate in patients treated with Rapamune 5 mg/day than in both of the comparator groups.

Among the adverse events that were reported at a rate of ≥3% and <20%, the following were more prominent in patients maintained on Rapamune 5 mg/day, when compared to patients on Rapamune 2 mg/day; epistaxis, lymphocele, insomnia, thrombotic thrombocytopenic purpura (hemolytic-uremic syndrome), skin ulcer, increased LDH, hypotension, facial edema.

The frequency of adverse reactions listed in the following table includes reactions reported in patients treated with Rapamune-based regimens.

In general, adverse events related to administration of Rapamune were dependent on dose/concentration.

The adverse reactions in the table below are listed in the MedDRA frequency categories.

System Organ Class	**Very Common ≥1/10**	**Common ≥1/100 to <1/10**	**Uncommon ≥1/1,000 to <1/100**	**Rare ≥1/10, 000 to <1/1 000**	**Frequency Not Known (Cannot be estimated from available data)**
Blood and Lymphatic System Disorders	Thrombocytopenia; anemia; leukopenia	Hemolytic uremic syndrome; neutropenia	Pancytopenia; thrombotic thrombocytopenic purpura		
Cardiac Disorders	Tachycardia	Pericardial effusion			
Gastrointestinal Disorders	Abdominal pain; constipation; diarrhea; nausea	Pancreatitis; stomatitis; ascites			
General Disorders and Administration Site Conditions	Edema; edema peripheral; pyrexia; pain; impaired healing				
Immune System Disorders		Hypersensitivity (including angioedema, anaphylactic reaction, and anaphylactoid reaction)			
Infections and Infestations	Pneumonia; fungal infection; viral infection; bacterial infection; herpes simplex; urinary tract infection	Sepsis; pyelonephritis; cytomegalovirus infection; herpes zoster	Mycobacterial infection (including tuberculosis); Epstein-Barr virus infection		
Investigations	Blood lactate dehydrogenase increased; blood creatinine increased; liver function test abnormal (including alanine aminotransferase increased and aspartate aminotransferase increased)				

System Organ Class	Very Common ≥1/10	Common ≥1/100 to <1/10	Uncommon ≥1/1,000 to <1/100	Rare ≥1/10, 000 to <1/1 000	Frequency Not Known (Cannot be estimated from available data)
Metabolism and Nutrition Disorders	Hypokalemia; hypophosphatemia; hyperlipidemia (including hypercholesterolemia); hyperglycemia; hypertriglyceridemia; fluid retention; diabetes mellitus				
Musculoskeletal, Connective Tissue and Bone Disorders	Arthralgia	Osteonecrosis			
Neoplasms Benign, Malignant and Unspecified (including cysts and polyps)		Squamous cell carcinoma of skin; basal cell carcinoma	Lymphoma; post-transplant lymphoproliferative disorder; malignant melanoma		Neuroendocrine carcinoma of the skin
Nervous System Disorders	Headache				Posterior reversible encephalopathy syndrome*
Renal and Urinary Disorders	Proteinuria		Nephrotic syndrome; focal segmental glomerulosclerosis		
Reproductive System and Breast Disorders	Menstrual disorder (including amenorrhea and menorrhagia)	Ovarian cyst			
Respiratory, Thoracic and Mediastinal Disorders		Pulmonary embolism; pneumonitis; pleural effusion; epistaxis	Pulmonary hemorrhage	Alveolar proteinosis	
Skin and Subcutaneous Tissue Disorders	Rash; acne		Dermatitis exfoliative	Hypersensitivity vasculitis	
Vascular Disorders	Hypertension; lymphocele	Venous thrombosis (including deep vein thrombosis)	Lymphedema		

*ADR identified post-marketing

Rapamune following cyclosporine withdrawal: The incidence of adverse reactions was determined through 60 months in a randomized, multicenter controlled trial in which 215 renal transplant patients received Rapamune as a maintenance regimen following cyclosporine withdrawal, and 215 patients received Rapamune with cyclosporine therapy. All patients were treated with corticosteroids. The safety profile prior to randomization (start of cyclosporine withdrawal) was similar to that of the 2 mg Rapamune groups in studies of Rapamune in combination with cyclosporine. Following randomization (at 3 months), patients who had cyclosporine eliminated from their therapy experienced significantly higher incidences of increased AST/SGOT and increased ALT/SGPT, liver damage, hypokalemia, thrombocytopenia, abnormal healing, acne, ileus, and joint disorder. Conversely, the incidence of acidosis, hypertension, cyclosporine toxicity, increased creatinine, abnormal kidney function, toxic nephropathy, edema, hyperuricemia, gout, and gum hyperplasia was

significantly higher in patients who remained on cyclosporine than those who had cyclosporine withdrawn from therapy. Mean systolic and diastolic blood pressure improved significantly following cyclosporine withdrawal.

Following cyclosporine withdrawal, (at 60 months), the incidence of Herpes zoster infection was significantly lower in patients receiving Rapamune following cyclosporine withdrawal, compared with patients who continued to receive Rapamune and cyclosporine.

The incidence of malignancies following cyclosporine withdrawal, based upon distinct categories, is presented in the following table. The incidence of lymphoma/lymphoproliferative disease was similar in all treatment groups. The overall incidence of malignancy, based upon the number of patients who had one or more malignancy, was lower in patients who had cyclosporine withdrawn than in patients receiving Rapamune plus cyclosporine (10.7% versus 15.8%, respectively).

INCIDENCE (%) OF MALIGNANCIES FOLLOWING CYCLOSPORINE WITHDRAWAL AT 60 MONTHS POST-TRANSPLANT[a]

Malignancy[d]	**Non-randomized[b] (n=95)**	**Rapamune with Cyclosporine Therapy[b] (n=215)**	**Rapamune Following Cyclosporine Withdrawal[c] (n=215)**
Lymphoma/lymphoproliferative disease	1.1	1.4	0.5
Skin Carcinoma			
Non-melanoma skin carcinoma	5.3	8.8	7.0
Melanoma	0.0	0.5	0.5
Other Malignancy	5.3	7.0	3.3

a: Includes patients who prematurely discontinued treatment.
b: Patients received Rapamune, cyclosporine and corticosteroids.
c: Patients received Rapamune and corticosteroids.
d: Patients may be counted in more than one category.

By 60 months, the incidence of non-skin malignancies (lymphoma/lymphoproliferative disease plus other malignancy from the table above) was significantly higher in the cohort who continued cyclosporine as compared with the cohort who had cyclosporine withdrawn (8.4% versus 3.8%, respectively). For skin cancer, the median time to first occurrence was significantly delayed (491 versus 1126 days) and when taking into account that a patient may have multiple skin cancers the relative risk (RR=0.346) for developing skin cancer was significantly lowered in the cyclosporine withdrawal group as compared with the group that continued cyclosporine.

Safety was assessed in a controlled trial (see **Section 5.1. Pharmacodynamic properties - Clinical Trials Data on Efficacy**) involving 448 patients who received at least one dose of study drug (safety population): 224 patients received at least one dose of sirolimus with tacrolimus, and 224 patients received at least one dose of sirolimus with cyclosporine. Overall, the incidence and nature of adverse events was similar to those seen in previous combination studies with Rapamune. Diarrhea and herpes simplex occurred significantly more frequently in patients who received sirolimus and tacrolimus, whereas, hypertension, cardiomegaly, lymphocele, increased creatinine, acne, urinary tract disorder, ovarian cyst, and calcineurin inhibitor toxicity occurred at a significantly higher rate in patients who received sirolimus and cyclosporine. The incidence of malignancy was low (1.3% in each group).

The safety and efficacy of conversion from calcineurin inhibitors to Rapamune in maintenance renal transplant patients has not been established.

In a study evaluating the safety and efficacy of conversion (6 to 120 months after transplantation) from calcineurin inhibitors to Rapamune (sirolimus target levels of 12-20 ng/mL by chromatographic assay) in maintenance renal transplant patients, enrollment was stopped in the subset of patients (n=90) with a baseline glomerular filtration rate of less than 40 mL/min. There was a higher rate of serious adverse events including pneumonia, acute rejection, graft loss and death in this Rapamune treatment arm (n=60, median time post-transplant 36 months).

In a study evaluating the safety and efficacy of conversion from tacrolimus to Rapamune 3 to 5 months post-renal transplant, a higher rate of acute rejection and new onset diabetes mellitus was observed following conversion to Rapamune (see **Section 5.1. Pharmacodynamic properties - Clinical Trials Data on Efficacy**).

The concomitant use of sirolimus with a calcineurin inhibitor may increase the risk of calcineurin inhibitor-induced HUS/TTP/TMA (see **Section 4.4. Special warnings and precaution for use**).

In patients with delayed graft function, Rapamune may delay recovery of renal function (see **Section 4.4. Special warnings and precaution for use - Renal Function**).

Other Clinical Experience
Azoospermia has been reported with the use of Rapamune and has been reversible upon discontinuation of Rapamune in most cases (see **Section 5.3. Preclinical safety data**).

Clostridium difficile enterocolitis has been reported in patients receiving sirolimus.

Interstitial Lung Disease
Cases of interstitial lung disease [including pneumonitis, and infrequently bronchiolitis obliterans organizing pneumonia (BOOP) and pulmonary fibrosis], some fatal, with no identified infectious etiology have occurred in patients receiving immunosuppressive regimens including Rapamune. In some cases, the interstitial lung disease has resolved upon discontinuation or dose reduction of Rapamune. The risk may be increased as the trough sirolimus level increases (see **Section 4.4. Special warnings and precaution for use - Interstitial Lung Disease**).

Latent Viral Infections
BK virus associated nephropathy and progressive multifocal leukoencephalopathy (PML) have been observed in patients receiving immunosuppressants, including Rapamune. These infection may be associated with serious or fatal outcomes, including renal graft loss (see **Section 4.4. Special warnings and precautions for use - Latent Viral Infections**).

Hepatotoxicity
Hepatotoxicity has been reported, including fatal hepatic necrosis with elevated trough sirolimus levels (i.e., exceeding therapeutic levels).

Abnormal Healing
Abnormal healing following transplant surgery has been reported, including fascial dehiscence, incisional hernia and anastomosis disruption (e.g., wound, vascular, airway, ureteral, biliary).

4.9. Overdose

There is limited experience with overdose. In general, the adverse effects of overdose are consistent with those listed in the **Section 4.8. Undesirable effects**. General supportive measures should be followed in all cases of overdose. Based on the poor aqueous solubility and high erythrocyte and plasma protein binding of sirolimus, it is anticipated that sirolimus is not dialyzable to any significant extent.

In mice and rats, the acute oral lethal dose (LD_{50}) was greater than 800 mg/kg.

4.10. Abuse and dependence

Rapamune has no potential for abuse. There is no evidence of dependence on Rapamune.

5. PHARMACOLOGICAL PROPERTIES

5.1. Pharmacodynamic properties

Immunosuppressant
ATC code: L04AH01

Mechanism of Action
Sirolimus inhibits T-lymphocyte activation and proliferation that occurs in response to antigenic and cytokine (Interleukin [IL]-2, IL-4, and IL-15) stimulation by a mechanism that is distinct from that of other immunosuppressants. Sirolimus also inhibits antibody production. In cells, sirolimus binds to the immunophilin, FK Binding Protein-12 (FKBP-12), to generate an immunosuppressive complex. The sirolimus: FKBP-12 complex has no effect on calcineurin activity. This complex binds to and inhibits the activation of the mTOR, a key regulatory kinase. This inhibition suppresses cytokine-driven T-cell proliferation, inhibiting the progression from the G_1 to the S phase of the cell cycle.

Studies in experimental models show that sirolimus prolongs allograft (kidney, heart, skin, islet, small bowel, pancreatico-duodenal, and bone marrow) survival in mice, rats, pigs, dogs, and/or primates. Sirolimus reverses acute rejection of heart and kidney allografts in rats and prolongs the graft survival in presensitized rats. In some studies, the immunosuppressive effect of sirolimus lasts up to 6 months after discontinuation of therapy. This tolerization effect is alloantigen specific.

In rodent models of autoimmune disease, sirolimus suppresses immune-mediated events associated with systemic lupus erythematosus, collagen-induced arthritis, autoimmune type I diabetes, autoimmune myocarditis, experimental allergic encephalomyelitis, graft-versus-host disease, and autoimmune uveoretinitis.

Clinical Trials Data on Efficacy
Rapamune Oral Solution with cyclosporine: The safety and efficacy of Rapamune Oral Solution for the prevention of organ rejection following renal transplantation were assessed in

two randomized, double-blind, multicenter, controlled trials. These studies compared-two dose levels of Rapamune Oral Solution (2 mg and 5 mg, once daily) with azathioprine (Study 1) or placebo (Study 2) when administered in combination with cyclosporine and corticosteroids. Study 1 was conducted in the United States at 38 sites. Seven hundred nineteen (719) patients were enrolled in this trial and randomized following transplantation; 284 were randomized to receive Rapamune Oral Solution 2 mg/day, 274 were randomized to receive Rapamune Oral Solution 5 mg/day, and 161 to receive azathioprine 2-3 mg/kg/day. Study 2 was conducted in Australia, Canada, Europe, and the United States, at a total of 34 sites. Five hundred seventy-six (576) patients were enrolled in this trial and randomized before transplantation; 227 were randomized to receive Rapamune Oral Solution 2 mg/day, 219 were randomized to receive Rapamune Oral Solution 5 mg/day, and 130 to receive placebo. In both studies, the use of antilymphocyte antibody induction therapy was prohibited. In both studies, the primary efficacy endpoint was the rate of efficacy failure in the first 6 months after transplantation. Efficacy failure was defined as the first occurrence of an acute rejection episode (confirmed by biopsy), graft loss, or death.

The tables below summarize the results of the primary efficacy analyses from these trials. Rapamune Oral Solution, at doses of 2 mg/day and 5 mg/day, significantly reduced the incidence of efficacy failure (statistically significant at the <0.025 level; nominal significance level adjusted for multiple dose comparisons) at 6 months following transplantation compared with both azathioprine and placebo.

INCIDENCE (%) OF THE PRIMARY ENDPOINT AT 6 AND 24 MONTHS FOR STUDY 1[a,b]

Parameter	**Rapamune Oral Solution 2 mg/day (n=284)**	**Rapamune Oral Solution 5 mg/day (n=274)**	**Azathioprine 2-3 mg/kg/day (n=161)**
Efficacy failure at 6 months[c]	18.7	16.8	32.3
Components of efficacy failure			
Biopsy-proven acute rejection	16.5	11.3	29.2
Graft loss	1.1	2.9	2.5
Death	0.7	1.8	0
Lost to follow-up	0.4	0.7	0.6
Efficacy failure at 24 months	32.8	25.9	36.0
Components of efficacy failure			
Biopsy-proven acute rejection	23.6	17.5	32.3
Graft loss	3.9	4.7	3.1
Death	4.2	3.3	0
Lost to follow-up	1.1	0.4	0.6

a: Patients received cyclosporine and corticosteroids.
b: Includes patients who prematurely discontinued treatment.
c: Primary endpoint.

INCIDENCE (%) OF THE PRIMARY ENDPOINT AT 6 AND 36 MONTHS FOR STUDY 2[a,b]

Parameter	Rapamune Oral Solution 2 mg/day (n=227)	Rapamune Oral Solution 5 mg/day (n=219)	Placebo (n=130)
Efficacy failure at 6 months[c]	30.0	25.6	47.7

Death	5.7	5.9	5.4
Lost to follow-up	0	0.9	0.8

a: Patients received cyclosporine and corticosteroids.
b: Includes patients who prematurely discontinued treatment.
c: Primary endpoint.

Patient and graft survival at 1 year were co-primary endpoints. The table below shows graft and patient survival at 1 and 2 years in Study 1, and 1 and 3 years in Study 2. The graft and patient survival rates were similar in patients treated with Rapamune and comparator-treated patients.

GRAFT AND PATIENT SURVIVAL (%) FOR STUDY 1 (12 AND 24 MONTHS) AND STUDY 2 (12 AND 36 MONTHS)[a,b]

Parameter	Rapamune Oral Solution 2 mg/day	Rapamune Oral Solution 5 mg/day	Azathioprine 2-3 mg/kg/day	Placebo
Study 1	(n=284)	(n=274)	(n=161)	
Graft survival				
Month 12	94.7	92.7	93.8	
Month 24	85.2	89.1	90.1	
Patient survival				
Month 12	97.2	96.0	98.1	
Month 24	92.6	94.9	96.3	
Study 2	(n=227)	(n=219)		(n=130)
Graft survival				
Month 12	89.9	90.9		87.7
Month 36	81.1	79.9		80.8
Patient survival				
Month 12	96.5	95.0		94.6
Month 36	90.3	89.5		90.8

a: Patients received cyclosporine and corticosteroids.
b: Includes patients who prematurely discontinued treatment.

The reduction in the incidence of first biopsy-confirmed acute rejection (BCAR) episodes in patients treated with Rapamune compared with the control groups included a reduction in all grades of rejection.

In Study 1, which was prospectively stratified by race within center, efficacy failure was similar for Rapamune Oral Solution 2 mg/day and lower for Rapamune Oral Solution 5 mg/day compared with azathioprine in Black patients. In Study 2, which was not prospectively stratified by race, efficacy failure was similar for both Rapamune Oral Solution doses compared with placebo in Black patients. The decision to use the higher dose of Rapamune Oral Solution in Black patients must be weighed against the increased risk of dose-dependent adverse events that were observed with the Rapamune Oral Solution 5 mg dose (see **Section 4.8. Undesirable effects**).

PERCENTAGE OF EFFICACY FAILURE BY RACE AT 6 MONTHS[a,b]

Parameter	**Rapamune Oral Solution 2 mg/day**	**Rapamune Oral Solution 5 mg/day**	**Azathioprine 2-3 mg/kg/day**	**Placebo**
Study 1				
Black (n=166)	34.9 (n=63)	18.0 (n=61)	33.3 (n=42)	
Non-Black (n=553)	14.0 (n=221)	16.4 (n=213)	31.9 (n=119)	
Study 2				
Black (n=66)	30.8 (n=26)	33.7 (n=27)		38.5 (n=13)
Non-Black (n=510)	29.9 (n=201)	24.5 (n=192)		48.7 (n=117)

a: Patients received cyclosporine and corticosteroids.
b: Includes patients who prematurely discontinued treatment.

Mean glomerular filtration rates (GFR) at one-year post-transplant were calculated by using the Nankivell equation for all subjects in Studies 1 and 2 who had serum creatinine measured at 12 months. In Studies 1 and 2, mean GFR, at 12 months, were lower in patients treated with cyclosporine and Rapamune Oral Solution compared with those treated with cyclosporine and the respective azathioprine or placebo control. Within each treatment group in both of these studies, mean GFR at one-year post transplant was lower in patients who experienced at least one episode of biopsy-proven acute rejection, compared to those who did not.

OVERALL CALCULATED GLOMERULAR FILTRATION RATES (CC/MIN) BY NANKIVELL EQUATION AT 12 MONTHS POST TRANSPLANT[a,b]

Parameter	**Rapamune Oral Solution 2 mg/day**	**Rapamune Oral Solution 5 mg/day**	**Azathioprine 2-3 mg/kg/day**	**Placebo**

Month 12	52.4 ± 1.5 (n=211)	51.5 ± 1.5 (n=199)		58.0 ± 2.1 (n=117)
Month 36	48.1 ± 1.8 (n=183)	46.1 ± 2.0 (n=177)		53.4 ± 2.7 (n=102)

a: Includes patients who prematurely discontinued treatment.
b: Patients who has a graft loss were included in the analysis with GFR set to 0.0.

These findings suggest that sirolimus potentiates the renal toxicity of cyclosporine. Therefore, cyclosporine withdrawal, 2 to 4 months after transplantation in patients with low to moderate immunological risk should be individualized and the decision to withdraw cyclosporine should be on the discretion of the clinician based on individual risk versus benefit profile of the patient.

Renal function should be monitored and appropriate adjustment of the immunosuppression regimen should be considered in patients with elevated or increasing serum creatinine levels (see **Section 4.4. Special warnings and precaution for use**).

Rapamune Tablets: The safety and efficacy of Rapamune Oral Solution and Rapamune Tablets for the prevention of organ rejection following renal transplantation were compared in a randomized multicenter controlled trial (Study 3). This study compared a single dose level (2 mg, once daily) of Rapamune Oral Solution and Rapamune Tablets when administered in combination with cyclosporine and corticosteroids. The study was conducted at 30 centers in Australia, Canada, and the United States. Four hundred seventy-seven (477) patients were enrolled in this study and randomized before transplantation; 238 patients were randomized to receive Rapamune Oral Solution 2 mg/day and 239 patients were randomized to receive Rapamune Tablets 2 mg/day. In this study, the use of antilymphocyte antibody induction therapy was prohibited. The primary efficacy endpoint was the rate of efficacy failure in the first 3 months after transplantation. Efficacy failure was defined as the first occurrence of an acute rejection episode (confirmed by biopsy), graft loss, or death.

The table below summarizes the result of the efficacy failure analysis at 3 and 6 months from this trial. The overall rate of efficacy failure at 3 months, the primary endpoint, in the tablet treatment group was equivalent to the rate in the oral solution treatment group.

INCIDENCE (%) OF THE PRIMARY ENDPOINT AT 3 AND 6 MONTHS: STUDY 3[a,b]

	Rapamune Oral Solution (n=238)	**Rapamune Tablets (n=239)**
Efficacy Failure at 3 months[c]	23.5	24.7
Components of efficacy failure		
Biopsy-proven acute rejection	18.9	17.6
Graft loss	3.4	6.3
Death	1.3	0.8
Efficacy Failure at 6 months	26.1	27.2
Components of efficacy failure		
Biopsy-proven acute rejection	21.0	19.2
Graft loss	3.4	6.3
Death	1.7	1.7

a: Patients received cyclosporine and corticosteroids.
b: Includes patients who prematurely discontinued treatment.
c: Efficacy failure at 3 months was the primary endpoint.

Graft and patient survival at 12 months were co-primary efficacy endpoints. There was no significant difference between the oral solution and tablet formulations for both graft and patient survival. Graft survival was 92.0% and 88.7% for the oral solution and tablet treatment groups, respectively. The patient survival rates in the oral solution and tablet treatment groups were 95.8% and 96.2%, respectively.

The mean GFR at 12 months, calculated by the Nankivell equation, were not significantly different for the oral solution group and for the tablet group. The table below summarizes the

mean GFR at one-year post-transplantation for all patients in Study 3 who had serum creatinine measured at 12 months.

OVERALL CALCULATED GLOMERULAR FILTRATION RATES (CC/MIN) BY NANKIVELL EQUATION AT 12 MONTHS POST TRANSPLANT: STUDY 3[a,b]

	Rapamune Oral Solution (n=150)	Rapamune Tablets (n=147)
Mean ± SEM	58.88 ± 1.68	59.05 ± 1.47

a: Includes patients who prematurely discontinued treatment.
b: Patients who had a graft loss were included in the analysis with GFR set to 0.0.

Rapamune maintenance regimen with cyclosporine withdrawal: The safety and efficacy of Rapamune as a maintenance regimen were assessed following cyclosporine withdrawal at 3 to 4 months post-renal transplantation. In a randomized multi-center controlled trial conducted at 57 centers in Australia, Canada, and Europe, five hundred twenty-five (525) patients were enrolled. All patients in this study received the tablet formulation. This study compared patients who were administered Rapamune, cyclosporine and corticosteroids—continuously with patients who received the same standardized therapy for the first 3 months after transplantation (pre-randomization period) followed by the withdrawal of cyclosporine. During cyclosporine withdrawal the Rapamune dosages were adjusted to achieve targeted sirolimus whole blood trough concentration ranges (16 to 24 ng/mL until Month 12, then 12 to 20 ng/mL thereafter through Month 60). At 3 months, 430 patients were equally randomized to either Rapamune with cyclosporine therapy or Rapamune as a maintenance regimen following cyclosporine withdrawal. Eligibility for randomization included no Banff 93 Grade III acute rejection episode or vascular rejection in the 4 weeks before random assignment; serum creatinine ≤4.5 mg/dL; and adequate renal function to support cyclosporine withdrawal (in the opinion of the investigator). The primary efficacy endpoint was graft survival at 12 months after transplantation. Secondary efficacy endpoints were the rate of biopsy-confirmed acute rejection, patient survival, incidence of efficacy failure (defined as the first occurrence of either biopsy-confirmed acute rejection, graft loss or death) and treatment failure (defined as the first occurrence of either discontinuation, acute rejection, graft loss or death).

The following table summarizes the resulting graft and patient survival at 12, 24, 36, 48 and 60 months for this trial. At 12, 24, and 36 months, graft and patient survival were similar for both groups.

GRAFT AND PATIENT SURVIVAL (%): STUDY 4 (CYCLOSPORINE WITHDRAWAL STUDY)[a]

Parameter	Rapamune with Cyclosporine Therapy (n=215)	Rapamune Following Cyclosporine Withdrawal (n=215)
Graft Survival		
Month 12[b]	95.3[c]	97.2
Month 24	91.6	94.0
Month 36[d]	87.0	91.6
Patient Survival		
Month 12	97.2	98.1
Month 24	94.4	95.8
Month 36[d]	91.6	94.0

a: Includes patients who prematurely discontinued treatment.
b: Primary efficacy endpoint.
c: Survival including loss to follow-up as an event.

d: Initial planned duration of the study.

The following table summarizes the results of first biopsy-proven acute rejection at 12 and 36 months. There was a significant difference in first biopsy-proven acute rejection between the two groups during post-randomization through 12 months. Most of the post-randomization acute rejections occurred in the first 3 months following randomization.

INCIDENCE OF FIRST BIOPSY-PROVEN ACUTE REJECTION (%) BY TREATMENT GROUP AT 36 MONTHS: STUDY 4 (CYCLOSPORINE WITHDRAWAL STUDY)[a,b]

Period	Rapamune with Cyclosporine Therapy (n=215)	Rapamune Following Cyclosporine Withdrawal (n=215)
Pre-randomization[c]	9.3	10.2
Post-randomization through 12 months[c]	4.2	9.8
Post-randomization from 12 to 36 months	1.4	0.5
Post-randomization through 36 months	5.6	10.2
Total at 36 months	14.9	20.5

a: Includes patients who prematurely discontinued treatment.
b: All patients received corticosteroids.
c: Randomization occurred at 3 months ± 2 weeks.

Patients receiving renal allografts with ≥4 HLA mismatches experienced significantly higher rates of acute rejection following randomization to the cyclosporine withdrawal group compared with patients who continued cyclosporine (15.3% versus 3.0%). Patients receiving renal allografts with ≤3 HLA mismatches, demonstrated similar rates of acute rejection between treatment groups (6.8% versus 7.7%) following randomization.

The following table summarizes the mean calculated GFR in Study 4 (cyclosporine withdrawal study).

CALCULATED GLOMERULAR FILTRATION RATES (mL/min) BY NANKIVELL EQUATION AT 12, 24, and 36 MONTHS POST TRANSPLANT: STUDY 4 (CYCLOSPORINE WITHDRAWAL STUDY)[a,b,c]

Parameter	Rapamune with Cyclosporine Therapy	Rapamune Following Cyclosporine Withdrawal
Month 12		
Mean ± SEM	53.2 ± 1.5 n=208	59.3 ± 1.5 n=203
Month 24		
Mean ± SEM	48.4 ± 1.7 n=203	58.4 ± 1.6 n=201
Month 36		
Mean ± SEM	47.0 ± 1.8 (n=196)	58.5 ± 1.9 (n=199)

a: Includes patients who prematurely discontinued treatment.
b: Patients who had a graft loss were included in the analysis and had their GFR set to 0.0.
c: All patients received corticosteroids.

The mean GFR at 12, 24, and 36 months, calculated by the Nankivell equation, was significantly higher for patients receiving Rapamune as a maintenance regimen following cyclosporine withdrawal than for those in the Rapamune with cyclosporine therapy group. Patients who had an acute rejection prior to randomization had a significantly higher GFR

following cyclosporine withdrawal compared to those in the Rapamune with cyclosporine group. There was no significant difference in GFR between groups for patients who experienced acute rejection post-randomization.

Although the initial protocol was designed for 36 months, there was a subsequent amendment to extend this study. The results for the cyclosporine withdrawal group at Months 48 and 60 were consistent with the results at Month 36. Fifty-two percent (112/215) of the patients in the Rapamune with cyclosporine withdrawal group remained on therapy to Month 60 and showed sustained GFR.

In an open-label, randomized, comparative, multicenter study where renal transplant patients were either converted from tacrolimus to sirolimus 3 to 5 months post-transplant or remained on tacrolimus, there was no significant difference in renal function at 2 years. There were more adverse events (99.2% versus 91.1%, p=0.002) and more discontinuations from the treatment due to adverse events (26.7% versus 4.1%, p<0.001) in the group converted to sirolimus compared to the tacrolimus group. The incidence of biopsy confirmed acute rejection was higher (p=0.020) for patients in the sirolimus group (11, 8.4%) compared to the tacrolimus group (2, 1.6%) through 2 years; most rejections were mild in severity (8 of 9 [89%] T-cell BCAR, 2 of 4 [50%] antibody mediated BCAR) in the sirolimus group. Patients who had both antibody-mediated rejection and T-cell-mediated rejection on the same biopsy were counted once for each category. More patients converted to sirolimus developed new onset diabetes mellitus defined as 30 days or longer of continuous or at least 25 days non-stop (without gap) use of any diabetic treatment after randomization, a fasting glucose ≥126 mg/dL or a non-fasting glucose ≥200 mg/dL after randomization (18.3% versus 5.6%, p=0.025). A lower incidence of squamous cell carcinoma of the skin was observed in the sirolimus group (0% versus 4.9%).

5.2. Pharmacokinetics

Sirolimus pharmacokinetic activity has been determined following oral administration in healthy subjects, pediatric patients, hepatically-impaired patients, and renal transplant patients.

Absorption

Following administration of Rapamune Oral Solution, sirolimus is rapidly absorbed, with a mean time-to-peak concentration (t_{max}) of approximately 1 hour after a single dose in healthy subjects and approximately 2 hours after multiple oral doses in renal transplant recipients. Following administration by tablet, sirolimus t_{max} was approximately 3 hours after single doses in healthy volunteers and multiple doses in renal transplant patients. The systemic availability of sirolimus was estimated to be approximately 14% after the administration of Rapamune Oral Solution. The mean bioavailability of sirolimus after administration of the tablet is about 27% higher relative to the oral solution. Sirolimus oral tablets are not bioequivalent to the oral solution; however, clinical equivalence has been demonstrated at the 2 mg dose level. (See **Section 5.1. Pharmacodynamic properties - Clinical Trials Data on Efficacy**)

Sirolimus concentrations, are dose proportional between 3 and 12 mg/m^2 after administration of Rapamune oral solution in stable renal transplant patients, and between 5 and 40 mg after administration of Rapamune tablets to healthy volunteers.

Food effects: In 22 healthy volunteers receiving Rapamune Oral Solution, a high-fat meal (860 kcal, 54.7% fat) altered the bioavailability characteristics of sirolimus. Compared with

fasting, a 34% decrease in the peak blood sirolimus concentration (C_{max}), a 3.5-fold increase in the time-to-peak concentration (t_{max}), and a 35% increase in total exposure (AUC) was observed. After administration of Rapamune Tablets and a high-fat meal in 24 healthy volunteers, C_{max}, t_{max}, and AUC showed increases of 65%, 32%, and 23%, respectively. Thus, a high-fat meal produced differences in the two formulations with respect to rate of absorption but not in extent of absorption. Evidence from a large randomized multicenter controlled trial comparing Rapamune oral solution to tablets supports that the differences in absorption rates do not affect the efficacy of the drug.

To minimize variability, Rapamune should be taken consistently with or without food. Bioequivalence testing based on AUC and C_{max} showed that sirolimus administered with orange juice is equivalent to administration with water. Grapefruit juice reduces CYP3A4 mediated drug metabolism and potentially enhances P-gp mediated drug counter-transport from enterocytes of the small intestine and must not be taken with Rapamune (see **Section 4.5. Interaction with other medicinal products and other forms of interaction**).

Distribution

The mean (±SD) blood-to-plasma ratio of sirolimus was 36 (±17.9) in stable renal allograft recipients after administration of oral solution, indicating that sirolimus is extensively partitioned into formed blood elements. The mean volume of distribution (V_{ss}/F) of sirolimus is 12 ± 7.52 L/kg. Sirolimus is extensively bound (approximately 92%) to human plasma proteins. In human whole blood, the binding of sirolimus was shown mainly to be associated with serum albumin (97%), α_1-acid glycoprotein, and lipoproteins.

Metabolism

Sirolimus is a substrate for both cytochrome P450 IIIA4 (CYP3A4) and P-glycoprotein. Sirolimus is extensively metabolized by O-demethylation and/or hydroxylation. Seven (7) major metabolites, including hydroxy, demethyl, and hydroxydemethyl, are identifiable in whole blood. Some of these metabolites are also detectable in plasma, fecal, and urine samples. The glucuronide and sulfate conjugates are not present in any of the biologic matrices. Sirolimus is the major component in human whole blood and contributes to more than 90% of the immunosuppressive activity.

Elimination

After a single dose of [^{14}C] sirolimus by oral solution in healthy subjects, the majority (91%) of radioactivity was recovered from the feces, and only a minor amount (2.2%) was excreted in urine. The mean ± SD terminal elimination half-life ($t_{½}$) of sirolimus after multiple dosing by Rapamune oral solution in stable renal transplant patients was estimated to be about 62 ± 16 hours.

Pharmacokinetics in Renal Transplant Patients

Mean (±SD) pharmacokinetic parameters for sirolimus oral solution given daily in combination with cyclosporine and corticosteroids in renal transplant patients were determined at Months 1, 3, and 6 after transplantation. There were no significant differences in C_{max}, t_{max}, AUC, or CL/F with respect to treatment group or month. After daily administration of Rapamune in renal transplant patients by oral solution and tablet, estimates of C_{max}, AUC, and CL/F did not appear to be different; but t_{max} was significantly different.

Mean whole blood sirolimus trough concentrations in patients receiving Rapamune with a loading dose of three times the maintenance dose achieved steady-state concentrations within 24 hours after the start of dose administration.

The pharmacokinetic parameters of sirolimus in adult renal transplant patients following multiple dosing with Rapamune 2 mg daily, in combination with cyclosporine and corticosteroids, is summarized in the following table.

MEAN ± SD STEADY-STATE SIROLIMUS PHARMACOKINETIC PARAMETERS IN ADULT RENAL TRANSPLANT PATIENTS FOLLOWING RAPAMUNE 2 MG DAILY[a,b]

	Multiple Dose (daily dose)
	Solution **Tablets**
C_{max} (ng/mL)	14.4 ± 5.3 15.0 ± 4.9
t_{max} (hr)	2.1 ± 0.8 3.5 ± 2.4
AUC (ng•h/mL)	194 ± 78 230 ± 67
C_{min} (ng/mL)[c]	7.1 ± 3.5 7.6 ± 3.1
CL/F (mL/h/kg)	173 ± 50 139 ± 63

a: In presence of cyclosporine administered 4 hours before Rapamune dosing.
b: Based on data collected at months 1 and 3 post-transplantation.
c: Average C_{min} over 6 months.

Whole blood trough sirolimus concentrations, as measured by LC/MS/MS in renal transplant patients, were significantly correlated with $AUC_{\tau,ss}$. Upon repeated, twice-daily administration without an initial loading dose in a multiple-dose study, the average trough concentration of sirolimus increases approximately 2- to 3-fold over the initial 6 days of therapy, at which time steady-state is reached. A loading dose of 3 times the maintenance dose will provide near steady-state concentrations within 1 day in most patients.

Sirolimus Concentrations (Chromatographic Equivalent) Observed in Phase 3 Clinical Studies
The following sirolimus concentrations (chromatographic equivalent) were observed in phase III clinical studies (see **Section 5.1. Pharmacodynamic properties - Clinical Trials Data on Efficacy**).

SIROLIMUS WHOLE BLOOD TROUGH CONCENTRATIONS OBSERVED IN RENAL TRANSPLANT PATIENTS ENROLLED IN PHASE 3 STUDIES

Patient Population (Study number)	Treatment	Year 1		Year 3	
		Mean (ng/mL)	10^{th} – 90^{th} percentiles (ng/mL)	Mean (ng/mL)	10^{th} – 90^{th} percentiles (ng/mL)
(Studies 1 & 2)	Rapamune (2 mg/day) + Cyclosporine	7.2	3.6 – 11	–	–
	Rapamune (5 mg/day) + Cyclosporine	14	8 – 22	–	–
Low-to-moderate risk (Study 3)	Rapamune + Cyclosporine	8.6	5 – 13[a]	9.1	5.4 – 14
	Rapamune alone	19	14 – 22[a]	16	11 – 22
High risk (Study 4)	Rapamune + Cyclosporine	15.7 11.8 11.5	5.4 – 27.3[b] 6.2 – 16.9[c] 6.3 – 17.3[d]	–	–

a: Months 4 through 12
b: Up to Week 2; observed Cyclosporine C_{min} was 217 (56 – 432) ng/mL
c: Week 2 to Week 26; observed Cyclosporine C_{min} range was 174 (71 – 288) ng/mL
d: Week 26 to Week 52; observed Cyclosporine C_{min} was 136 (54.5 – 218) ng/mL

Average Rapamune doses and sirolimus whole blood trough concentrations for tablets administered daily in combination with cyclosporine or tacrolimus and corticosteroids in high-risk renal transplant patients (Study 5; see **Section 5.1. Pharmacodynamic properties - Clinical Trials Data on Efficacy**) are summarized in the table below.

AVERAGE RAPAMUNE DOSES AND SIROLIMUS TROUGH CONCENTRATIONS (MEAN ± SD) IN HIGH-RISK RENAL TRANSPLANT PATIENTS AFTER MULTIPLE-DOSE TABLET ADMINISTRATION

	Rapamune with Tacrolimus Therapy	Rapamune with Cyclosporine Therapy
Rapamune Dose (mg/day)		
Months 3 to 6[a]	6.5 ± 3.0	5.1 ± 2.4
Months 9 to 12[b]	6.5 ± 3.0	5.0 ± 2.3
Sirolimus C_{min} (ng/mL)[c]		
Months 3 to 6	11.5 ± 6.2	11.8 ± 4.2
Months 9 to 12	10.7 ± 3.6	11.2 ± 3.8

a: n=110 in Rapamune/Tacrolimus group, n=109 in Rapamune/Cyclosporine Group.
b: n=117 in Rapamune/Tacrolimus group, n=127 in Rapamune/Cyclosporine Group.
c: Expressed by chromatography.

Patients treated with the combination of Rapamune and tacrolimus required larger Rapamune doses to achieve the target sirolimus concentrations than patients treated with the combination of Rapamune and cyclosporine.

Special Populations

Patients with Renal Impairment

There is minimal renal excretion of drug or its metabolites. The pharmacokinetics of sirolimus are very similar in various populations with renal function ranging from normal to absent (dialysis patients).

Patients with Hepatic Impairment

Sirolimus oral solution (15 mg) was administered as a single oral dose to subjects with normal hepatic function and to patients with Child-Pugh classification A (mild), B (moderate), or C (severe) primary hepatic impairment.

Compared with the values in the normal hepatic function group, the patients with mild, moderate, or severe hepatic impairment had 43%, 94%, and 189% higher mean values for sirolimus AUC, respectively, and $t_{1/2}$ with no significant differences in mean C_{max}. As the severity of hepatic impairment increased, there were steady increases in mean sirolimus $t_{1/2}$, and decreases in the mean sirolimus clearance normalized for body weight (CL/F/kg).

The maintenance dose of Rapamune should be reduced by approximately one third in patients with mild to moderate hepatic impairment and by approximately one half in patients with severe hepatic impairment based on decreased clearance (see **Section 4.2. Posology and method of administration**). In patients with hepatic impairment, it is necessary that sirolimus whole blood trough levels be monitored. In patients with severe hepatic impairment, consideration should be given to monitoring every 5 to 7 days for a longer period of time after dose adjustment or after loading dose due to the delay in reaching steady state because of the prolonged half-life.

Children

Sirolimus pharmacokinetic data were collected in concentration-controlled trials of pediatric renal transplant patients who were also receiving cyclosporine and corticosteroids. The target ranges for trough concentrations were either 10-20 ng/mL for the 21 children receiving tablets, or 5-15 ng/mL for the one child receiving oral solution. The children aged 6-11 years (n=8) received mean ± SD doses of 1.75 ± 0.71 mg/day (0.064 ± 0.018 mg/kg, 1.65 ± 0.43 mg/m^2). The children aged 12-18 years (n=14) received mean ± SD doses of 2.79 ± 1.25 mg/day (0.053 ± 0.0150 mg/kg, 1.86 ± 0.61 mg/m^2). At the time of sirolimus blood sampling for pharmacokinetic evaluation, the majority (80%) of these pediatric patients received the sirolimus dose at 16 hours after the once daily cyclosporine dose.

SIROLIMUS PHARMACOKINETIC PARAMETERS (MEAN ± SD) IN PEDIATRIC RENAL TRANSPLANT PATIENTS (MULTIPLE DOSE CONCENTRATION CONTROL)[a,b]

Age (y)	**n**	**Body weight (kg)**	**$C_{max,ss}$ (ng/mL)**	**$t_{max,ss}$ (h)**	**$C_{min,ss}$ (ng/mL)**	**$AUC_{\tau,ss}$ (ng•h/mL)**	**CL/F[c] (mL/h/kg)**	**CL/F[c] (L/h/m^2)**
6-11	8	27 ± 10	22.1 ± 8.9	5.88 ± 4.05	10.6 ± 4.3	356 ± 127	214 ± 129	5.4 ± 2.8
12-18	14	52 ± 15	34.5 ± 12.2	2.7 ± 1.5	14.7 ± 8.6	466 ± 236	136 ± 57	4.7 ± 1.9

a: Sirolimus co-administered with cyclosporine oral solution (e.g., Neoral® Oral Solution) and/or cyclosporine capsule (e.g., Neoral® Soft Gelatin Capsules).
b: As measured by Liquid Chromatographic/Tandem Mass Spectrometric Method (LC/MS/MS).
c: Oral-dose clearance adjusted by either body weight (kg) or body surface area (m^2).

The Table below summarizes pharmacokinetic data obtained in pediatric dialysis patients with chronically impaired renal function receiving Rapamune by oral solution.

SIROLIMUS PHARMACOKINETIC PARAMETERS (MEAN ± SD) IN PEDIATRIC PATIENTS WITH STABLE CHRONIC RENAL FAILURE MAINTAINED ON HEMODIALYSIS OR PERITONEAL DIALYSIS
(1, 3, 9, 15 MG/M^2 SINGLE DOSE)*

Age Group (y)	N	t_{max} (h)	$t_{1/2}$ (h)	CL/F (mL/h/kg)
5-11	9	1.1 ± 0.5	71 ± 40	580 ± 450
12-18	11	0.79 ± 0.17	55 ± 18	450 ± 232

* All subjects received sirolimus oral solution.

Geriatric
Clinical studies of Rapamune did not include a sufficient number of patients >65 years of age to determine whether they will respond differently than younger patients. After the administration of Rapamune Oral Solution, sirolimus trough concentration data in 35 renal transplant patients >65 years of age were similar to those in the adult population (n=822) from 18 to 65 years of age. Similar results were obtained after the administration of Rapamune Tablets to 12 renal transplant patients >65 years of age compared with adults (n=167) 18 to 65 years of age.

Gender
After the administration of Rapamune Oral Solution, sirolimus oral dose clearance in males was 12% lower than that in females; male subjects had a significantly longer $t_{1/2}$ than did female subjects (72.3 hours versus 61.3 hours). A similar trend in the effect of gender on sirolimus oral dose clearance and $t_{1/2}$ was observed after the administration of Rapamune Tablets. Dose adjustments based on gender are not recommended.

Race
In large phase III trials using Rapamune Oral Solution and cyclosporine oral solution (e.g., Neoral® Oral Solution) and/or cyclosporine capsules (e.g., Neoral® Soft Gelatin Capsules), there were no significant differences in mean trough sirolimus concentrations over time between Black (n=139) and non-Black (n=724) patients during the first 6 months after transplantation at sirolimus doses of 2 mg/day and 5 mg/day. Similarly, after administration of Rapamune Tablets (2 mg/day) in a phase III trial, mean sirolimus trough concentrations over 6 months were not significantly different among Black (n=51) and non-Black (n=128) patients.

5.3. Preclinical safety data

Carcinogenesis, Mutagenesis, and Impairment of Fertility

Carcinogenicity
Carcinogenicity studies were conducted in mice and rats. In an 86-week female mouse study at dosages of 0, 12.5, 25 and 50/6 (dosage lowered from 50 to 6 mg/kg/day at Week 31 due to infection secondary to immunosuppression) there was a statistically significant increase in malignant lymphoma at all dose levels (approximately 16 to 135 times the clinical doses adjusted for body surface area) compared to controls.

In the second mouse study at dosages of 0, 1, 3 and 6 mg/kg (approximately 3 to 16 times the clinical dose adjusted for body surface area), hepatocellular adenoma and carcinoma (males), were considered Rapamune related. In the 104-week rat study at dosages of 0, 0.05, 0.1 and 0.2 mg/kg/day (approximately 0.4 to 1 times the clinical dose adjusted for body surface area),

there was a statistically significant increased incidence of testicular adenoma in the 0.2 mg/kg/day group.

Mutagenicity
Sirolimus was not genotoxic in the *in vitro* bacterial reverse mutation assay, the Chinese hamster ovary cell chromosomal aberration assay, the mouse lymphoma cell forward mutation assay, or the *in vivo* mouse micronucleus assay.

Reproductive Toxicology
There was no effect on fertility in female rats following the administration of sirolimus at dosages up to 0.5 mg/kg (approximately 1 to 3 times the clinical doses adjusted for body surface area). In male rats, there was no significant difference in fertility rate compared to controls at a dosage of 2 mg/kg (approximately 4 to 11 times the clinical doses adjusted for body surface area). Reductions in testicular weights and/or histological lesions (e.g., tubular atrophy and tubular giant cells) were observed in rats following dosages of 0.65 mg/kg (approximately 1 to 3 times the clinical doses adjusted for body surface area) and above and in a monkey study at 0.1 mg/kg (approximately 0.4 to 1 times the clinical doses adjusted for body surface area) and above. Sperm counts were reduced in male rats following the administration of sirolimus for 13 weeks at a dosage of 6 mg/kg (approximately 12 to 32 times the clinical doses adjusted for body surface area), but showed improvement by 3 months after dosing was stopped.

6. PHARMACEUTICAL PARTICULARS

6.1. List of excipients

The inactive ingredients in Rapamune Tablets include sucrose, lactose monohydrate, polyethylene glycol 8000 powdered, calcium sulfate anhydrous, microcrystalline cellulose, pharmaceutical glaze (shellac solution 4# cut), talc, titanium dioxide, magnesium stearate, povidone (K29/32), poloxamer 188, polyethylene glycol (macrogol) type 20,000, glyceryl monooleate (60%), carnauba wax, vitamin E (*dl-alpha* tocopherol), alcohol denatured 23A*, water purified*, mineral spirits odorless, ink-red opacode S-1-15095, yellow iron (ferric) oxide [0.5 mg only], brown iron (ferric) oxide [0.5 mg only] and water for injection*.

*Removed during processing. Does not appear in the finished dosage form.

6.2. Incompatibilities

Not applicable.

6.3. How Supplied

Rapamune Tablets are available as follows:

0.5 mg, tan, triangular, sugar coated tablets branded “RAPAMUNE 0.5 mg” in red ink on one side;
1 mg, white, triangular-shaped tablets marked “RAPAMUNE 1 mg” on one side.

Packaged in Polyvinyl chloride (PVC), polyethylene (PE) and Aclar blister with aluminium foil lidding.

NDC # 0008-1041 -05, bottle of 100 tablets.
NDC # 0008-1041 -10, Redipak® cartons of 100 tablets (10 blister cards of 10 tablets each).
Item # 66894 unit carton 3 x 10's: Rapamune 1 mg.
Item # 66948 unit carton 10 x 10's: Rapamune 0.5 mg and Rapamune 1 mg.

Not all products may be marketed.

6.4. Storage and shelf-life

Shelf-life: Refer to outer carton.

Rapamune Tablet 0.5 mg should be stored at or below 30°C. Rapamune Tablet 1 mg should be stored below 30°C. Use cartons to protect blister cards and strips from light. Dispense in a tight, light-resistant container as defined in the USP.

6.5. Special precautions for disposal and other handling

Since Rapamune is not absorbed through the skin, there are no special precautions. However, if direct contact with the skin or mucous membranes occurs, wash thoroughly with soap and water; rinse eyes with plain water.

Package leaflet: Information for the user

Rapamune tablet 0.5 mg
Rapamune tablet 1 mg
sirolimus

Read all of this leaflet carefully before you start taking this medicine because it contains important information for you.
- Keep this leaflet. You may need to read it again.
- If you have any further questions, ask your doctor or pharmacist.
- This medicine has been prescribed for you only. Do not pass it on to others. It may harm them, even if their signs of illness are the same as yours.
- If you get any side effects, talk to your doctor or pharmacist. This includes any possible side effects not listed in this leaflet. See section 4.

What is in this leaflet

1. What Rapamune is and what it is used for
2. What you need to know before you take Rapamune
3. How to take Rapamune
4. Possible side effects
5. How to store Rapamune
6. Contents of the pack and other information

1. What Rapamune is and what it is used for

Rapamune contains the active substance sirolimus, which belongs to a group of medicines called immunosuppressants. It helps to control your body's immune system after you have received a kidney transplant.

Rapamune is used to prevent your body from rejecting transplanted kidneys and is normally used initially in a regimen with other immunosuppressant medicines called corticosteroids and cyclosporine in patients at low to moderate immunologic risk.

2. What you need to know before you take Rapamune

Do not take Rapamune

- if you are allergic to sirolimus or any of the other ingredients of this medicine (listed in section 6).

Warnings and precautions

Talk to your doctor or pharmacist before taking Rapamune:

- If you have any liver problems or have had a disease which may have affected your liver, please tell your doctor as this may affect the dose of Rapamune that you receive and may result in having additional blood tests.
- If you are taking medicines such as ketoconazole, voriconazole, itraconazole, erythromycin, telithromycin, clarithromycin, rifampicin, rifabutin or cannabidiol, please

tell your doctor as this may affect the dose of Rapamune that you receive. Also refer to below section **Other medicines and Rapamune**.
- If you have a body mass index (BMI) greater than 30 kg/m^2, you may be at increased risk of abnormal wound healing.
- If you are considered to be at high risk for kidney rejection, such as if you had a previous transplant that was lost to rejection.

Rapamune, like other immunosuppressive medicines, may decrease your body's ability to fight infection, and may increase the risk of developing cancer of the lymphoid tissues and skin.

Exposure to sunlight and UV light should be limited by covering your skin with clothing and using a sunscreen with a high protection factor because of the increased risk for skin cancer.

Hypersensitivity reactions, including anaphylactic/anaphylactoid reactions, rapid swelling under the skin (angioedema), exfoliative dermatitis, and hypersensitivity vasculitis, have been associated with the administration of sirolimus.

Your doctor will perform tests to monitor the levels of Rapamune in your blood. Your doctor will also perform tests to monitor your kidney function, your blood fat (cholesterol and/or triglycerides) levels and possibly your liver function, during treatment with Rapamune.

You may happen to have lymph fluid collection around the lower belly (Lymphocele), a known surgical complication of renal transplantation, occurred significantly more often in a dose-related fashion in Rapamune-treated patients.

Cases of interstitial lung disease (including inflammation in the lungs, and infrequently bronchiolitis obliterans organizing pneumonia [BOOP], a rare inflammatory lung disorder and pulmonary fibrosis), some fatal, with no identified infectious etiology have occurred in patients receiving immunosuppressive regimens including Rapamune. In some cases, the interstitial lung disease has resolved upon discontinuation or dose reduction of Rapamune.

Children and adolescents

Safety and efficacy of Rapamune in pediatric patients below the age of 13 years have not been established. It is recommended that sirolimus whole blood trough levels be monitored if used in pediatric patients <13 years of age.

Other medicines and Rapamune

Tell your doctor or pharmacist if you are taking, have recently taken or might take any other medicines.

Some medicines can interfere with the action of Rapamune and, therefore, dose adjustment of Rapamune may be required. In particular, you should inform your doctor or pharmacist if you are taking any of the following:

- any other immunosuppressant medicines.
- antibiotics or antifungal medicines used to treat infection e.g., erythromycin, troleandomycin, rifapentine, clotrimazole, fluconazole. It is not recommended that

Rapamune be taken with clarithromycin, telithromycin, rifampicin, rifabutin, itraconazole, ketoconazole or voriconazole.
- any high blood pressure medicines or medicines for heart problems including nicardipine, verapamil and diltiazem.
- anti-epileptic medicines including carbamazepine, phenobarbital, phenytoin.
- medicines used to treat ulcers or other gastrointestinal disorders such as cisapride, cimetidine, metoclopramide.
- bromocriptine (used in the treatment of Parkinson's disease and various hormonal disorders), danazol (used in the treatment of gynecological disorders), or protease inhibitors (e.g., for HIV and hepatitis C such as ritonavir, indinavir, boceprevir, and telaprevir).
- St. John's Wort (*Hypericum perforatum*).
- letermovir (an antiviral medicine to prevent getting ill from cytomegalovirus).
- cannabidiol (uses amongst others include treatment of seizures).

The use of live vaccines should be avoided with the use of Rapamune. Before vaccinations, please inform your doctor or pharmacist that you are receiving Rapamune.

The use of Rapamune may lead to increased levels of cholesterol and triglycerides (blood fats) in your blood that may require treatment. Medicines known as "statins" and "fibrates" used to treat elevated cholesterol and triglycerides have been associated with an increased risk of muscle breakdown (rhabdomyolysis). Please inform your doctor if you are taking medicines to lower your blood fats.

The combined use of Rapamune with angiotensin-converting enzyme (ACE) inhibitors (a type of medicine used to lower blood pressure) may result in allergic reactions. Please inform your doctor if you are taking any of these medicines.

Concomitant use of sirolimus with a calcineurin inhibitor (such as cyclosporine, tacrolimus) may increase the risk of calcineurin inhibitor-induced Hemolytic Uremic Syndrome (kidney damage with low blood platelets and low red blood cell counts, with or without rash) / Thrombotic Thrombocytopenic Purpura (low blood platelets, with or without rash) / Thrombotic Microangiopathy (formation of microscopic blood clots in capillaries and small arteries).

Rapamune with food and drink

Rapamune should be taken consistently, either with or without food. If you prefer to take Rapamune with food, then you should always take it with food. If you prefer to take Rapamune without food, then you should always take it without food. Food can affect the amount of medicine that gets into your bloodstream, and taking your medicine in a consistent way means that the blood levels of Rapamune remain more stable.

Rapamune should not be taken with grapefruit juice.

Pregnancy, breast-feeding and fertility

Rapamune should not be used during pregnancy unless clearly necessary. You must use an effective method of contraception during treatment with Rapamune and for 12 weeks after treatment has stopped. If you are pregnant or breast-feeding, think you may be pregnant or

are planning to have a baby, ask your doctor or pharmacist for advice before taking this medicine.

It is not known whether Rapamune passes into breast milk. A decision should be made whether to discontinue nursing or to discontinue the drug, taking into account the importance of the drug to the mother.

Decreased sperm count has been associated with the use of Rapamune and usually returns to normal once treatment is stopped.

Driving and using machines

Although Rapamune treatment is not expected to affect your ability to drive, if you have any concerns please consult your doctor.

3. How to take Rapamune

Always take this medicine exactly as your doctor has told you. Check with your doctor or pharmacist if you are not sure.

Your doctor will decide exactly what dose of Rapamune you must take and how often to take it. Follow your doctor's instructions exactly, and never change the dose yourself.

Rapamune is for oral use only.

Do not crush, chew, or split the tablets. Inform your doctor if you have difficulty taking the tablet.

Rapamune should be taken consistently, either with or without food.

<u>Kidney Transplant</u>
Your doctor will give you an initial dose of 6 mg as soon as possible after the kidney transplant operation. Then you will need to take 2 mg of Rapamune each day, until otherwise directed by your doctor. Your dose will be adjusted depending on the level of Rapamune in your blood. Your doctor will need to perform blood tests to measure Rapamune concentrations.

If you are also taking cyclosporine microemulsion, then you must take the two medicines approximately 4 hours apart.

It is recommended that Rapamune be used first in combination with cyclosporine and corticosteroids. After 2 to 4 months, your doctor may progressively discontinue cyclosporine over 4 to 8 weeks.

If you take more Rapamune than you should

If you have taken more medicine than you were told contact a doctor or go to the nearest hospital emergency department straight away. Always take the labelled medicine bottle with you, even if it is empty.

If you forget to take Rapamune

If you forget to take Rapamune, take it as soon as you remember, but not within 4 hours of the next dose of cyclosporine microemulsion. After that, continue to take your medicines as usual. Do not take a double dose to make up for a forgotten dose, and always take Rapamune and cyclosporine microemulsion approximately 4 hours apart. If you miss a dose of Rapamune completely, you should inform your doctor.

If you stop taking Rapamune

Do not stop taking Rapamune unless your doctor tells you to, as you risk losing your transplant.

If you have any further questions on the use of this medicine, ask your doctor or pharmacist.

4. Possible side effects

Like all medicines, this medicine can cause side effects, although not everybody gets them.

Allergic reactions

You should **see your doctor immediately** if you experience symptoms, such as swollen face, tongue and/or back of the mouth (pharynx) and/or difficulties in breathing (angioedema), or a skin condition whereby the skin can peel off (exfoliative dermatitis). These may be symptoms of a serious allergic reaction.

Kidney damage with low blood cell counts (thrombocytopenic purpura/hemolytic uremic syndrome)

When taken with medicines called calcineurin inhibitors (cyclosporine or tacrolimus), Rapamune may increase the risk of kidney damage with low blood platelets and low red blood cell counts, with or without rash (thrombocytopenic purpura/hemolytic uremic syndrome). If you experience symptoms, such as bruising or rash, changes in your urine, or changes in behavior, or any others that are serious, unusual or prolonged, contact your doctor.

Infections

Rapamune reduces your body's own defense mechanisms. Consequently your body will not be as good as normal at fighting infections. So if you are taking Rapamune, you may therefore catch more infections than usual, such as infections of the skin, mouth, stomach and intestines, lungs and urinary tract (see list below). You should contact your doctor if you experience symptoms that are serious, unusual, or prolonged.

Side effect frequencies

Very common: may affect more than 1 in 10 people

- Lymph fluid collection around the lower belly
- Swelling of the body including hands and feet
- Pain

- Fever
- Headache
- Increased blood pressure
- Stomach pain, diarrhea, constipation, nausea
- Low red blood cells, low blood platelets
- Increased fat in the blood (cholesterol and/or triglycerides), increased blood sugar, low blood potassium, low blood phosphorus, increased lactate dehydrogenase in the blood, increased creatinine in the blood
- Joint pain
- Acne
- Urinary tract infection
- Pneumonia and other bacterial, viral, and fungal infections
- Viral infection of the mouth
- A reduced number of infection-fighting cells in the blood (white blood cells)
- Diabetes
- Fluid retention
- Abnormal tests of liver function, elevated AST and/or ALT liver enzymes
- Rash
- Elevated protein in the urine
- Menstrual disorders (including absent, infrequent or heavy periods)
- Slow healing (this may include separation of the layers of a surgical wound or stitch line)
- Rapid heart rate

Common: may affect up to 1 in 10 people

- Infections (including life-threatening infections)
- Blood clots in the legs
- Blood clots in the lung
- Mouth sores
- Fluid collection in the abdomen
- Kidney damage with low blood platelets and low red blood cell counts, with or without rash (hemolytic uremic syndrome)
- Low levels of a type of white blood cells called neutrophils
- Deterioration of bone
- Inflammation that may lead to lung damage, fluid around the lung
- Skin cancer
- Kidney infection
- Ovarian cysts
- Fluid collection in the sac around the heart, that in some cases may decrease the heart's ability to pump blood
- Inflammation of the pancreas
- Allergic reactions
- Shingles
- Cytomegalovirus infection
- Nosebleed

Uncommon: may affect up to 1 in 100 people

- Cancer of the lymph tissue (lymphoma/post-transplant lympho-proliferative disorder), combined lowering of red blood cells, white blood cells and blood platelets
- Malignant melanoma, a type of skin cancer
- Bleeding from the lung
- Protein in the urine, occasionally severe and associated with side effects, such as swelling
- Scarring in the kidney that may reduce kidney function
- Too much fluid collecting in the tissues due to irregular lymph function
- Low blood platelets, with or without rash (thrombocytopenic purpura)
- Serious allergic reactions that can cause peeling of the skin
- Tuberculosis
- Epstein-Barr virus infection

Rare: may affect up to 1 in 1,000 people

- Protein build-up in the air sacs of the lungs that may interfere with breathing
- Serious allergic reactions that can affect blood vessels (see above paragraph on allergic reactions)

Not known: frequency cannot be estimated from the available data

- Posterior reversible encephalopathy syndrome (PRES), a serious nervous system syndrome that has the following symptoms: headache, nausea, vomiting, confusion, seizures, and visual loss. Should any of these occur together, please contact your physician.
- Neuroendocrine carcinoma of the skin, a rare type of cancer that forms on or just beneath the skin, usually in parts of the body that have been exposed to the sun.

Reporting of side effects

If you get any side effects, talk to your doctor, pharmacist or nurse. This includes any possible side effects not listed in this leaflet.

5. How to store Rapamune

Keep this medicine out of the sight and reach of children.

Refer to outer carton for the shelf-life.

Rapamune Tablet 0.5 mg should be stored at or below 30°C. Rapamune Tablet 1 mg should be stored below 30°C.

Keep the blister in the outer carton in order to protect from light.

Do not throw away any medicines via wastewater or household waste. Ask your pharmacist how to throw away medicines you no longer use. These measures will help protect the environment.

6. Contents of the pack and other information

What Rapamune contains

The active substance is sirolimus.
Each Rapamune 0.5 mg coated tablet contains 0.5 mg of sirolimus.
Each Rapamune 1 mg coated tablet contains 1 mg of sirolimus.

The other ingredients are:

Sucrose, lactose monohydrate, polyethylene glycol 8000 powdered, calcium sulfate anhydrous, microcrystalline cellulose, pharmaceutical glaze (shellac solution 4# cut), talc, titanium dioxide, magnesium stearate, povidone (K29/32), poloxamer 188, polyethylene glycol (macrogol) type 20,000, glyceryl monooleate (60%), carnauba wax, vitamin E (*dl-alpha* tocopherol), alcohol denatured 23A*, water purified*, mineral spirits odorless, ink-red opacode S-1-15095, yellow iron (ferric) oxide [0.5 mg only], brown iron (ferric) oxide [0.5 mg only] and water for injection*.

*Removed during processing. Does not appear in the finished dosage form.

What Rapamune looks like and contents of the pack

Rapamune tablets are available as follows:

0.5 mg, tan, triangular, sugar coated tablets branded “RAPAMUNE 0.5 mg” in red ink on one side;
1 mg, white, triangular-shaped tablets marked “RAPAMUNE 1 mg” on one side.

Packaged in Polyvinyl chloride (PVC), polyethylene (PE) and Aclar blister with aluminium foil lidding.

NDC # 0008-1041 -05, bottle of 100 tablets.
NDC # 0008-1041 -10, Redipak® cartons of 100 tablets (10 blister cards of 10 tablets each).
Item # 66894 unit carton 3 x 10’s: Rapamune 1 mg.
Item # 66948 unit carton 10 x 10’s: Rapamune 0.5 mg and Rapamune 1 mg.

Not all products may be marketed.
