

MEDROL®

Methylprednisolone

4mg Tablets

16mg Tablets

Italy

Date : October 2016, V4

Common Export Pack

SUMMARY OF PRODUCT CHARACTERISTICS

Summary of the product characteristics

1. NAME OF THE MEDICINAL PRODUCT

MEDROL 4 mg tablets

MEDROL 16 mg tablets

2. QUALITATIVE AND QUANTITATIVE COMPOSITION

Each methylprednisolone tablet contains 4 mg of methylprednisolone.

Each methylprednisolone tablet contains 16 mg of methylprednisolone.

Excipients with known effect:

Medrol 4 mg lactose, sucrose

Medrol 16 mg lactose monohydrate, sucrose.

For a full list of excipients, see section 6.1.

3. PHARMACEUTICAL FORM

Tablet for oral administration

The tablets of Medrol 4 mg tablets are semi oval, elliptical, white color, with the inscription "Medrol 4" on one side and a score cross on the other side.

The tablets of Medrol 16 mg tablets are convex, elliptical, white color, with the inscription "Medrol 16" on one side and a score cross on the other side.

4. CLINICAL PARTICULARS

4.1 Therapeutic indications

Endocrine Disorders

Primary or secondary adrenocortical insufficiency (hydrocortisone or cortisone is the first choice; synthetic analogs may be used in conjunction with mineralocorticoids where applicable; in infancy mineralocorticoid supplementation is of particular importance).

- congenital adrenal hyperplasia
- nonsuppurative thyroiditis
- hypercalcemia associated with cancer

Rheumatic Disorders

As adjunctive therapy for short-term administration (to tide the patient over an acute episode or exacerbation) in:

- psoriatic arthritis, rheumatoid arthritis (selected cases may require low-dose maintenance therapy); acute nonspecific tenosynovitis, ankylosing spondylitis, acute and subacute bursitis, acute gouty arthritis.

Collagen Diseases

During an exacerbation or as maintenance therapy in selected cases of:

- systemic lupus erythematosus
- acute rheumatic carditis

Dermatologic Diseases

- pemphigus
- exfoliative dermatitis
- bullous dermatitis herpetiformis

- mycosis fungoides
- severe erythema multiforme (Stevens-Johnson syndrome)
- severe psoriasis

Allergic States

Control of severe or incapacitating allergic conditions intractable to adequate trials of conventional treatment:

- seasonal or perennial allergic rhinitis
- contact dermatitis, atopic dermatitis;
- bronchial asthma;
- serum sickness;
- angioneurotic edema;
- urticaria

Ophthalmic Diseases

Severe acute and chronic allergic and inflammatory processes involving the eye and its adnexa such as:

- allergic corneal marginal ulcers;
- allergic conjunctivitis;
- herpes zoster ophthalmicus;
- keratitis;
- anterior segment inflammation;
- chorioretinitis;
- diffuse posterior uveitis and choroiditis;
- optic neuritis; iritis and iridocyclitis;
- sympathetic ophthalmia.

Respiratory Disease

- symptomatic sarcoidosis;
- Löffler's syndrome not manageable by other means;
- berylliosis;
- fulminating or disseminated pulmonary tuberculosis when used concurrently with appropriate antituberculous chemotherapy

Hematologic Disorders

- idiopathic thrombocytopenic and secondary thrombocytopenia in adults;
- acquired (autoimmune) hemolytic anemia;
- erythroblastopenia;
- congenital (erythroid) hypoplastic anemia.

Neoplastic Diseases

For palliative management of:

- leukemia and lymphomas in adults;
- acute leukemia of childhood.

Edematous States

- To induce a diuresis or remission of proteinuria in the nephrotic syndrome, without uremia, or the idiopathic type or that due to lupus erythematosus.

Miscellaneous

- tuberculous meningitis with subarachnoid block or impending block when used concurrently with appropriate antituberculous chemotherapy;
- systemic dermatomyositis (polymyositis).

Medrol also finds application in the case of:

- Respiratory Diseases
pulmonary emphysema, in cases where the bronchial edema or bronchospasm have a significant role.
Diffuse interstitial pulmonary fibrosis (Hamman-Rich syndrome)
- Edematous States:
in combination with diuretics to induce a diuresis in cases of:
liver cirrhosis with ascites, congestive heart failure.
- Gastrointestinal Diseases:
To tide the patient over a critical period of the disease in ulcerative colitis, intractable sprue, regional enteritis.

4.2 Posology and method of administration

Posology

The initial dosage of MEDROL (methylprednisolone) can vary from 4 to 48 mg per day depending on the severity of the disease. The initial dosage should be maintained or adjusted until a satisfactory response is not known.

If after a reasonable period of time the clinical response is not satisfactory, MEDROL should be discontinued and the patient subjected to other therapy. It must be emphasized that the dosage is variable and should be individualized on the basis of the disease treated and on the basis of patient response.

After a positive response, it is necessary to determine a maintenance dosage decreasing the initial dosage of the drug with small decreases at appropriate time intervals until reaching the lowest effective dose to maintain an adequate clinical response. The important is the check and the constant adaptation of drug dosage.

Situations that could necessitate dosage adjustments include: changes in clinical status secondary to remission or exacerbation of the disease process, individual response to the drug, effect on the patient of exposure to stressful situations not directly linked to the entity of the disease; in this last situation may be necessary to increase the dosage of MEDROL for a period of time compliant to the condition of the patient. If after a long-term therapy the treatment must be discontinued, is recommend a gradual decrease rather than abrupt decrease.

Initial Dose

Maintenance dose

Rheumatic Disorders

- rheumatoid arthritis

severe

12-16 mg

6-12 mg

midly severe

8-10 mg

4-8 mg

slight	6-8 mg	2-6 mg
teenagers	6-10 mg	2-8 mg
- disseminated	20-40 mg	8-20 mg
lupus erythematosus		
- Acute rheumatic fever	0.5 mg for each 450 g of body weight, until the serum mucoproteins amount to 6 mg% and the sedimentation rate remains normal for a week	

Allergic States

- severe seasonal asthma	16-40 mg	
- severe hay fever	“	
- exfoliative dermatitis	“	
- contact dermatitis	“	
- congenital asthma	12-40 mg	4-16 mg
- intractable allergic rhinitis	“	“
- widespread atopic dermatitis	“	“
- widespread infant eczema	8-12 mg	

Inflammatory ophthalmic diseases (involving the posterior segment)

- Acute	12-40 mg	
- Chronic	12-40 mg	2-12 mg

Miscellaneous

- adrenogenital syndrome		4-12 mg
- ulcerative colitis	16-60 mg	
- leukemia	12-16 mg	
- nephrosis	20-60 mg (10-14 days or until diuresis appears)	12-40 mg (3 consecutive days per week for 6-12 months)

4.3. Contraindications

- Hypersensitivity to the active substance or to any excipient listed in the paragraph 6.1.
- Systemic fungal infections.

Administration of live or live, attenuated vaccines is contraindicated in patients receiving immunosuppressive doses of corticosteroids.

4.4 Special warnings and precautions for use

Immunosuppressant Effects/Increased Susceptibility to Infections

Corticosteroids may increase susceptibility to infection, may mask some signs of infection, and new infections may appear during their use: must be considered the possibility of establishing an appropriate antibiotic therapy.

During the use of corticosteroids may occur a decrease resistance and inability to localize infection when corticosteroids are used. Infections caused by any pathogen, including viral, bacterial and fungal infections, or caused by protozoa or helminths, localized in any part of the body, may be associated with the use of corticosteroids alone or in combination with other immunosuppressive agents that affect cellular immunity, humoral immunity, or

neutrophil function. These infections may be mild, but can be severe and at times fatal. With increasing doses of corticosteroids, the rate of occurrence of infectious complications increases.

Persons who are on drugs which suppress the immune system are more susceptible to infections than healthy individuals. Chicken pox and measles, for example, can have a more serious or even fatal course in non-immune children or adults on corticosteroids. During treatment with corticosteroids, patients should not be vaccinated against smallpox. Due to the possibility of the risk of neurological complications and a decrease of the antibody response do not perform other procedures of immunization in patients receiving corticosteroid therapy, especially at high doses.

Administration of live or live, attenuated vaccines is contraindicated in patients receiving immunosuppressive doses of corticosteroids. Killed or inactivated vaccines may be administered to patients receiving immunosuppressive doses of corticosteroids; however, the response to such vaccines may be diminished. Indicated immunization procedures may be undertaken in patients receiving non-immunosuppressive doses of corticosteroids.

The use of corticosteroids in active tuberculosis should be restricted to those cases of fulminating or disseminated tuberculosis in which the corticosteroid is used for the management of the disease in conjunction with an appropriate antituberculous regimen. If corticosteroids are indicated in patients with latent tuberculosis or tuberculin reactivity, close observation is necessary as reactivation of the disease may occur. During prolonged corticosteroid therapy, these patients should receive chemoprophylaxis.

Kaposi's sarcoma has been reported to occur in patients receiving corticosteroid therapy. Discontinuation of corticosteroids may result in clinical remission.

Immune System

Allergic reactions (eg, angioedema) may occur.

Because rare instances of skin reactions and anaphylactic/anaphylactoid reactions have occurred in patients receiving corticosteroid therapy,¹ appropriate precautionary measures should be taken prior to administration, especially when the patient has a history of allergy to any drug.

Endocrine System

In patients on corticosteroid therapy subjected to unusual stress, increased dosage of rapidly acting corticosteroids before, during, and after the stressful situation is indicated.

Pharmacologic doses of corticosteroids administered for prolonged periods may result in hypothalamic-pituitary-adrenal (HPA) suppression (secondary adrenocortical insufficiency). The degree and duration of adrenocortical insufficiency produced is variable among patients and depends on the dose, frequency, time of administration, and duration of glucocorticoid therapy. In addition, acute adrenal insufficiency leading to a fatal outcome may occur if glucocorticoids are withdrawn abruptly.

Drug-induced adrenocortical insufficiency may be minimized by gradual reduction of dosage. This type of relative insufficiency may persist for months after discontinuation of therapy; therefore, in any situation of stress occurring during that period, hormone therapy should be reinstated.

A steroid “withdrawal syndrome,” seemingly unrelated to adrenocortical insufficiency, may also occur following abrupt discontinuance of glucocorticoids. This syndrome includes symptoms such as: anorexia, nausea, vomiting, lethargy, headache, fever, joint pain, desquamation, myalgia, weight loss, and/or hypotension. These effects are thought to be due to the sudden change in glucocorticoid concentration rather than to low corticosteroid levels.

Because glucocorticoids can produce or aggravate Cushing’s syndrome, glucocorticoids should be avoided in patients with Cushing’s disease.

There is an enhanced effect of corticosteroids on patients with hypothyroidism.

In the course of therapy is suggested to gradually reduce the dosage in order to find the lowest maintenance dose.

Metabolism and Nutrition

Corticosteroids, including methylprednisolone, can increase blood glucose, worsen pre-existing diabetes, and predispose those on long-term corticosteroid therapy to diabetes mellitus.

Psychiatric

Psychic derangements may appear when corticosteroids are used, ranging from euphoria, insomnia, mood swings, personality changes, and severe depression to frank psychotic manifestations. Also, existing emotional instability or psychotic tendencies may be aggravated by corticosteroids.

Potentially severe psychiatric adverse reactions may occur with systemic steroids (see section 4.8). Symptoms typically emerge within a few days or weeks of starting treatment. Most reactions recover after either dose reduction or withdrawal, although specific treatment can be necessary. Psychological effects have been reported upon withdrawal of corticosteroids; the frequency is unknown. Patients/caregivers can be encouraged to seek medical attention if psychological symptoms develop in the patient, especially if depressed mood or suicidal ideation is suspected. Patients/caregivers should be alert to possible psychiatric disturbances that may occur either during or immediately after dose tapering/withdrawal of systemic steroids.

Nervous System

Corticosteroids should be used with caution in patients with myasthenia gravis (see also the paragraph Musculoskeletal Effects) and in patients with seizure disorders.

Although controlled clinical trials have shown corticosteroids to be effective in speeding the resolution of acute exacerbations of multiple sclerosis, they do not show that corticosteroids affect the ultimate outcome or natural history of the disease. The studies do show that relatively high doses of corticosteroids are necessary to demonstrate a significant effect. (See section 4.2).

There have been reports of epidural lipomatosis in patients taking corticosteroids, typically with long-term use at high doses.

Ophthalmic Diseases

Prolonged use of corticosteroids may produce posterior subcapsular cataracts and nuclear cataracts (particularly in children), exophthalmos, or increased intraocular pressure, which may result in glaucoma with possible damage to the optic nerves. Establishment of

secondary fungal and viral infections of the eye may also be enhanced in patients receiving glucocorticoids. Corticosteroids should be used cautiously in patients with ocular herpes simplex because of possible corneal perforation.

Corticosteroid therapy has been associated with central serous chorioretinopathy, which can lead to retinal detachment.

Cardiac and vascular system

Adverse effects of glucocorticoids on the cardiovascular system, such as dyslipidemia and hypertension, may predispose treated patients with existing cardiovascular risk factors to additional cardiovascular effects, if high doses and prolonged courses are used. Accordingly, corticosteroids should be employed judiciously in such patients and attention should be paid to risk modification and additional cardiac monitoring if needed. Low dose and alternate day therapy may reduce the incidence of complications in corticosteroid therapy.

Systemic corticosteroids should be used with caution, and only if strictly necessary, in cases of congestive heart failure.

Thrombosis, including venous thromboembolism has been reported to occur with corticosteroids. As a result corticosteroids should be used with caution in patients who have or may be predisposed to thromboembolic disorders.

Steroids should be used with caution in patients with hypertension.

Gastrointestinal and hepatobiliary system

There is no universal agreement on whether corticosteroids per se are responsible for peptic ulcers encountered during therapy; however, glucocorticoid therapy may mask the symptoms of peptic ulcer so that perforation or hemorrhage may occur without significant pain. In combination with NSAIDs, the risk of developing gastrointestinal ulcers is increased.

Corticosteroids should be used with caution in nonspecific ulcerative colitis if there is a probability of impending perforation, abscess or other pyogenic infection, diverticulitis, fresh intestinal anastomoses, or active or latent peptic ulcer.

High doses of corticosteroids may produce acute pancreatitis.

Musculoskeletal system

An acute myopathy has been reported with the use of high doses of corticosteroids, most often occurring in patients with disorders of neuromuscular transmission (eg, myasthenia gravis), or in patients receiving concomitant therapy with anticholinergics, such as neuromuscular blocking drugs (eg, pancuronium) (see Nervous System Effects). This acute myopathy is generalized, may involve ocular and respiratory muscles, and may result in quadriplegia. Elevations of creatine kinase may occur. Clinical improvement or recovery after stopping corticosteroids may require weeks to years. Osteoporosis is a common but infrequently recognized adverse effect associated with a long-term use of large doses of glucocorticoid.

Renal and Urinary system

Corticosteroids should be used with caution in patients with renal insufficiency.

Investigations

Average and large doses of hydrocortisone or cortisone can cause elevation of blood pressure, salt and water retention, and increased excretion of potassium. These effects are less likely to occur with the synthetic derivatives except when used in large doses. Dietary salt restriction and potassium supplementation can be necessary. All corticosteroids increase calcium excretion.

Injury, Poisoning and Procedural Complications

Systemic corticosteroids are not indicated for, and therefore should not be used to treat traumatic brain injury. A multicenter study revealed an increased mortality at 2 weeks and 6 months after injury in patients administered methylprednisolone sodium succinate compared to placebo. A casual association with methylprednisolone sodium succinate treatment has not been established.

Other

Because complications of treatment with glucocorticoids are dependent on the size of the dose and the duration of treatment, a risk/benefit decision must be made in each individual case as to dose, the posology and duration of therapy should be used.

The lowest possible dose of corticosteroid should be used to control the condition under treatment and when reduction in dosage is possible, the reduction should be gradual.

Aspirin and nonsteroidal anti-inflammatory agents should be used cautiously in conjunction with corticosteroids.

The administration of corticosteroids may reduce or abolish the response to skin tests. Pheochromocytoma crisis, which can be fatal, has been reported after administration of systemic corticosteroids. Corticosteroids should only be administered to patients with suspected or identified pheochromocytoma after an appropriate risk/benefit evaluation.

Pediatric population

Growth and development of infants and children on prolonged corticosteroid therapy should be carefully observed.

Growth may be suppressed in children receiving long-term daily, divided dose glucocorticoid therapy and use of such regimen should be restricted to the most urgent indications.

Infants and children on prolonged corticosteroid therapy are at special risk from raised intracranial pressure.

High doses of corticosteroids may produce pancreatitis in children. 

Use in the elderly

Caution is recommended with prolonged treatment with corticosteroids in the elderly due to a potential increased risk of osteoporosis, as well as an increased risk of water retention, thus possibly resulting in hypertension.

Important information about some of the ingredients

This medicine contains lactose. Patients with rare hereditary problems of galactose intolerance, the Lapp lactase deficiency or glucose-galactose malabsorption should not take this medicine.

This medicine contains sucrose. Patients with rare hereditary problems of fructose intolerance, glucose-galactose malabsorption and sucrase isomaltase insufficiency should not take this medicine.

4.5 Interactions with other medicinal products and other forms of interaction

Methylprednisolone is a cytochrome P450 enzyme (CYP) substrate and is mainly metabolized by the CYP3A4 enzyme. CYP3A4 is the dominant enzyme of the most abundant CYP subfamily in the liver of adult humans. It catalyzes 6 β -hydroxylation of steroids, the essential Phase I metabolic step for both endogenous and synthetic corticosteroids. Many other compounds are also substrates of CYP3A4, some of which (as well as other drugs) have been shown to alter glucocorticoid metabolism by induction (upregulation) or inhibition of the CYP3A4 enzyme.

CYP3A4 INHIBITORS - Drugs that inhibit CYP3A4 activity generally decrease hepatic clearance and increase the plasma concentration of CYP3A4 substrate medications, such as methylprednisolone. In the presence of a CYP3A4 inhibitor, the dose of methylprednisolone may need to be titrated to avoid steroid toxicity.

CYP3A4 INDUCERS - Drugs that induce CYP3A4 activity generally increase hepatic clearance, resulting in decreased plasma concentration of medications that are substrates for CYP3A4. Coadministration may require an increase in methylprednisolone dosage to achieve the desired result.

CYP3A4 SUBSTRATES - In the presence of another CYP3A4 substrate, the hepatic clearance of methylprednisolone may be affected, with corresponding dosage adjustments required. It is possible that adverse events associated with the use of either drug alone may be more likely to occur with coadministration.

NON-CYP3A4-MEDIATED EFFECTS – Other interactions and effects that occur with methylprednisolone are described in

Table 1 below.

Table 1 provides a list and descriptions of the most common and/or clinically important drug interactions or effects with methylprednisolone.

Table 1. Important drug or substance interactions/effects with methylprednisolone

Drug Class or Type - DRUG or SUBSTANCE	Interaction/Effect
Antibacterial - ISONIAZID	CYP3A4 INHIBITOR. In addition, there is a potential effect of methylprednisolone to increase the acetylation rate and clearance of isoniazid.
Antibiotic, Antitubercular - RIFAMPIN	CYP3A4 INDUCER
Anticoagulants (oral)	The effect of methylprednisolone on oral anticoagulants is variable. There are reports of enhanced as well as diminished effects of anticoagulants when given concurrently with corticosteroids. Therefore, coagulation indices should be monitored to maintain the desired anticoagulant effects.
Anticonvulsants	

Drug Class or Type - DRUG or SUBSTANCE	Interaction/Effect
- CARBAMAZEPINE	CYP3A4 INDUCER (and SUBSTRATE)
Anticonvulsants - PHENOBARBITAL - PHENYTOIN	CYP3A4 INDUCERS
Anticholinergics - NEUROMUSCULAR BLOCKERS	Corticosteroids may influence the effect of anticholinergics. 1) An acute myopathy has been reported with the concomitant use of high doses of corticosteroids and anticholinergics, such as neuromuscular blocking drugs (for additional information see section 4.4). 2) Antagonism of the neuromuscular blocking effects of pancuronium and vecuronium has been reported in patients taking corticosteroids. This interaction may be expected with all competitive neuromuscular blockers.
Anticholinesterases	Steroids may reduce the effects of anticholinesterases in myasthenia gravis.
Antidiabetics	Because corticosteroids may increase blood glucose concentrations, dosage adjustments of antidiabetic agents may be required.
Antiemetic - APREPITANT - FOSAPREPITANT	CYP3A4 INHIBITORS (and SUBSTRATES)
Antifungal - ITRACONAZOLE - KETOCONAZOLE	CYP3A4 INHIBITORS (and SUBSTRATES)
Antivirals - HIV-PROTEASE INHIBITORS	CYP3A4 INHIBITORS (and SUBSTRATES) 1) HIV-protease inhibitors, such as indinavir and ritonavir, may increase plasma concentrations of corticosteroids. 2) Corticosteroids may induce the metabolism of HIV-protease inhibitors resulting in reduced plasma concentrations.
Aromatase inhibitors - AMINOGLUTETHIMIDE	Aminoglutethimide-induced adrenal suppression may exacerbate endocrine changes caused by prolonged glucocorticoid treatment.
Calcium Channel Blocker - DILTIAZEM	CYP3A4 INHIBITOR (and SUBSTRATE)
Contraceptives (oral) - ETHINYLESTRADIOL/ NORETHINDRONE	CYP3A4 INHIBITOR (and SUBSTRATE)
- GRAPEFRUIT JUICE	CYP3A4 INHIBITOR
Immunosuppressant - CYCLOSPORINE	CYP3A4 INHIBITOR (and SUBSTRATE) 1) Mutual inhibition of metabolism occurs with concurrent use of cyclosporine and methylprednisolone, which may increase the plasma concentrations of either or both drugs. Therefore, it is possible that adverse events associated with the use of either drug alone may be more likely to occur upon coadministration. 2) Convulsions have been reported with concurrent use of methylprednisolone and cyclosporine.
Immunosuppressant - CYCLOPHOSPHAMIDE - TACROLIMUS	CYP3A4 SUBSTRATES
Macrolide Antibacterial - CLARITHROMYCIN	CYP3A4 INHIBITORS (and SUBSTRATES)

Drug Class or Type - DRUG or SUBSTANCE	Interaction/Effect
- ERYTHROMYCIN	
Macrolide Antibacterial - TROLEANDOMYCIN	CYP3A4 INHIBITOR
NSAIDs (nonsteroidal anti-inflammatory drugs) - high-dose ASPIRIN (acetylsalicylic acid)	1) There may be increased incidence of gastrointestinal bleeding and ulceration when corticosteroids are given with NSAIDs. 2) Methylprednisolone may increase the clearance of high-dose aspirin, which can lead to decreased salicylate serum levels. Discontinuation of methylprednisolone treatment can lead to raised salicylate serum levels, which could lead to an increased risk of salicylate toxicity.
Potassium-depleting agents	When corticosteroids are administered concomitantly with potassium-depleting agents (i.e., diuretics), patients should be observed closely for development of hypokalemia. There is also an increased risk of hypokalemia with concurrent use of corticosteroids with amphotericin B, xanthenes, or beta2 agonists.

4.6 Fertility, pregnancy and lactation

Fertility

Corticosteroids have been shown to impair fertility in animal studies (see section 5.3).

Pregnancy

Some animal studies have shown that corticosteroids, when administered to the mother at high doses, may cause fetal malformations (see section 5.3). Adequate human reproductive studies have not been done with corticosteroids. Since there is inadequate evidence of safety in human pregnancy, this drug should be used in pregnancy only if clearly needed.

Some corticosteroids readily cross the placenta. One retrospective study found an increased incidence of low birth weights in infants born of mothers receiving corticosteroids. Infants born to mothers, who have received substantial doses of corticosteroids during pregnancy must be carefully observed and evaluated for signs of adrenal insufficiency, although neonatal adrenal insufficiency appears to be rare in infants who were exposed in utero to corticosteroids.

Cataracts have been observed in infants born to mothers undergoing long-term treatment with corticosteroids during pregnancy.

There are no known effects of corticosteroids on labor and delivery.

Breast-feeding

Corticoids are excreted in breast milk. Corticosteroids distributed into breast milk may suppress growth and interfere with endogenous glucocorticoid production in nursing infants. Since adequate reproductive studies have not been performed in humans with glucocorticoids, these drugs should be administered to nursing mothers only if the benefits of therapy are judged to outweigh the potential risks to the infant.

In pregnant women and in women who are breastfeeding the medicine should be administered in cases of real necessity under the direct supervision of a doctor.

4.7 Effects on ability to drive and use machines

The effect of corticosteroids on the ability to drive or use machinery has not been systematically evaluated. Undesirable effects, such as dizziness, vertigo, visual disturbances and fatigue are possible after treatment with corticosteroids. If affected, patients should not drive or operate machinery.

4.8 Undesirable effects

In the course of therapy with methylprednisolone, especially if intense and prolonged, were reported the following side effects with the following frequencies: Very common ($\geq 1/10$); common ($\geq 1/100, <1/10$), uncommon ($\geq 1/1000, <1/100$), rare ($\geq 1/10000, <1/1000$), not known (frequency cannot be estimated available data)

Infections and infestations:

common: infection

uncommon: opportunistic infection.

Immune system disorders:

unknown: drug hypersensitivity (including anaphylactic reaction and anaphylactoid reaction), suppression of reactions to skin tests.

Blood and lymphatic system disorders:

Not know: leukocytosis

Metabolism and nutrition disorders:

common: fluid retention, sodium retention.

unknown: alkalosis hypokalaemic, metabolic acidosis, glucose tolerance impaired, increased appetite (which may result in weight increased), increased requirements for insulin or oral hypoglycemic agents in diabetics. Decreased tolerance for carbohydrates and possible manifestation of latent diabetes mellitus and increased need for hypoglycemic medicine in diabetic patients.

Cardiac disorders:

unknown: alterations of electrolyte balance, which in rare cases can lead to hypertension and congestive cardiac failure (in susceptible patients).

Vascular disorders:

common: hypertension

unknown: hypotension, thrombosis

Respiratory, thoracic and mediastinal disorders:

unknown: hiccups, pulmonary embolism.

Musculoskeletal and connective tissue disorders:

common: growth retardation, muscular weakness;

unknown: arthralgia, muscle atrophy, myalgia, myopathy, neuropathic arthropathy, osteonecrosis, osteoporosis, pathologic fracture.

Gastrointestinal disorders:

common : complications affecting the gastrointestinal system, which may cause the starting or the activation of peptic ulcer (with possible peptic ulcer perforation and peptic ulcer haemorrhage).

unknown: abdominal distension, abdominal pain, diarrhoea, dyspepsia, gastric haemorrhage, intestinal perforation, nausea, oesophagitis, oesophagitis ulcerative, pancreatitis.

Skin and subcutaneous tissue disorders:

common: acne, skin atrophy

unknown: angioedema, ecchymosis, erythema, hirsutism, hyperhidrosis, petechiae, pruritus, rash, skin striae, urticaria.

Reproductive system and breast disorders:

unknown: menstruation irregular.

Nervous system disorders:

unknown: amnesia, cognitive disorder, convulsions, dizziness, headache, intracranial pressure increased (with Papilloedema [Benign intracranial hypertension]), epidural lipomatosis.

Psychiatric disorders:

common: affective disorder (including depressed mood and euphoric mood)

unknown: psychotic disorder (including mania, delusion, hallucination, and schizophrenia [aggravation of]), psychotic behaviour, affective disorder (including affect lability, psychological dependence, suicidal ideation), mental disorder, personality change, mood swings, confusional state, anxiety, abnormal behaviour, insomnia, irritability.

Endocrine disorders:

common: simil Cushingoid

unknown: hypopituitarism, steroid withdrawal syndrome.

Interference with the pituitary adrenal axis function, particularly in times of stress. Alteration of growth in the children.

Eye disorders:

common: cataract subcapsular:

unknown: exophthalmos, glaucoma, central serous chorioretinopathy.

Ear and labyrinth disorders:

unknown: vertigo

General disorders and administration site conditions:

common: impaired healing;

unknown: fatigue, malaise.

Investigations:

common: blood potassium decreased

unknown: alanine aminotransferase increased, aspartate aminotransferase increased, blood alkaline phosphatase increased, carbohydrate tolerance decreased, intraocular pressure increased, urine calcium increase.

Negativity of nitrogen balance.

Injury, poisoning and procedural complications:

unknown: spinal compression fracture, tendon rupture (particularly of the Achilles tendon).

Reporting of suspected adverse reactions

Reporting suspected adverse reactions after marketing authorisation of the medicinal product is important. It allows continued monitoring of the benefit/risk balance of the medicinal product. Healthcare professionals are asked to report any suspected adverse reactions according to their local country requirements.

4.9 Overdose

There is no clinical syndrome of acute overdose with corticosteroids. In case of acute overdose are possible cardiac arrhythmias and / or cardiovascular collapse.

Reports of acute toxicity and/or death following overdosage of corticosteroids are rare. In the event of overdosage, no specific antidote is available; treatment is supportive and symptomatic. Methylprednisolone is dialyzable.

5. PHARMACOLOGICAL PROPERTIES

MEDROL contains a synthetic glucocorticoid, the methylprednisolone, which is the 6-methyl derivative of prednisolone.

5.1 Pharmacodynamic properties

Drug therapeutic category: Systemic corticosteroids not associated - Glucocorticoids

ATC: H02AB04

Methylprednisolone is a potent anti-inflammatory steroid. It has greater anti-inflammatory potency than prednisolone and less tendency than prednisolone to induce sodium and water retention. The relative potency of methylprednisolone to hydrocortisone is at least four to one.

The natural glucocorticoids (hydrocortisone and cortisone) also have salt and water retention properties, and are used as replacement therapy in adrenocortical deficiency states. Their synthetic analogues are mainly used in many diseases for their potent anti-inflammatory action. The glucocorticoids induce important metabolic effects, and modify the immune responses to different stimulation.

5.2 Pharmacokinetic properties

Methylprednisolone pharmacokinetics is linear, independent of route of administration.

Absorption:

Methylprednisolone is rapidly absorbed and the maximum plasma methylprednisolone concentration is achieved around 1.5 to 2.3 hours across doses following oral administration in normal healthy adults. The absolute bioavailability of methylprednisolone in normal healthy subjects is generally high (82% to 89%) following oral administration.

Distribution: Methylprednisolone is widely distributed into the tissues, crosses the blood-brain barrier, and is secreted in breast milk. Its apparent volume of distribution is approximately 1.4 L/kg. The plasma protein binding of methylprednisolone in humans is approximately 77%.

Metabolism:

In humans, methylprednisolone is metabolized in the liver to inactive metabolites; the major ones are 20 α -hydroxymethylprednisolone and 20 β -hydroxymethylprednisolone. Metabolism in the liver occurs primarily via the CYP3A4 enzyme (for a list of drug interactions based on CYP3A4-mediated metabolism, see section 4.5).

Methylprednisolone, like many CYP3A4 substrates, may also be a substrate for the ATP-binding cassette (ABC) transport protein p-glycoprotein, influencing tissue distribution and interactions with other medicines.

Elimination:

The mean elimination half-life for total methylprednisolone is in the range of 1.8 to 5.2 hours. Total clearance is approximately 5 to 6 mL/min/kg.

5.3 Preclinical safety data

Based on conventional studies of safety pharmacology, repeated-dose toxicity no unexpected hazards were identified. The toxicities seen in the repeated-dose studies are those expected to occur with continued exposure to exogenous adrenocortical steroids.

Carcinogenic potential:

Long-term studies in animals have not been performed to evaluate carcinogenic potential.

Mutagenic potential:

There was no evidence of a potential for genetic and chromosome mutations when tested in limited studies performed in bacterial and mammalian cells.

Reproductive toxicity:

Corticosteroids have been shown to reduce fertility when administered to rats.

Corticosteroids have been shown to be teratogenic in many species when given in doses equivalent to the human dose. In animal reproduction studies, glucocorticoids such as methylprednisolone have been shown to induce malformations (cleft palate, skeletal malformations) and intra-uterine growth retardation (see section 4.6).

6. PHARMACEUTICAL PARTICULARS

6.1. List of excipients

4 mg tablets: **lactose monohydrate**, corn starch, , **sucrose**, calcium stearate.
16 mg tablets: **lactose monohydrate**, **sucrose**, vaseline oil, calcium stearate, corn starch.

6.2 Incompatibilities

While not applying to the pharmaceutical form of MEDROL, methylprednisolone, however, is incompatible in solution with various drugs. The compatibility depends on various factors such as, the concentration of the drugs, the pH of the solution and the temperature. You should not dilute and do not mix methylprednisolone with other solutions.

6.3 Shelf life

Do not use Medrol after the expiry date which is stated on the carton label after EXP:.. The expiry date refers to the last day of that month.

6.4 Special precautions for storage

Store below 30°C.

6.5 Nature and contents of container

-High density polyethylene (HDPE) bottle containing 10 tablets of 4 mg;
Blisters: Aluminum/clear PVC foil:
30 tablets of 4 mg
20 tablets of 16 mg
Not all Pack Sizes may be marketed.

6.6 Special precautions for disposal and other handling

Keep out of the sight and reach of children.

Any unused product or waste material should be disposed of in accordance with local requirements.

THIS IS A MEDICAMENT

- Medicament is a product which affects your health and its consumption contrary to instructions is dangerous for you.
- Follow strictly the doctor's prescription, the method of use and the instructions of the Pharmacist who sold the medicament.
- The doctor and the Pharmacist are experts in medicines, their benefits and risks.
- Do not by yourself interrupt the period of treatment prescribed.
- Do not repeat the same prescription without consulting your doctor.

Keep all medicaments out of reach and sight of children

Council of Arab Health Ministers

Union of Arabic Pharmacists
